The Labor Market for Directors and Externalities in Corporate Governance

Doron Levit and Nadya Malenko*

March 2013

ABSTRACT

This paper studies how directors’ reputational concerns in the labor market affect board structure, corporate governance, and firm value. In our setting, directors affect their firms’ governance, and governance, in turn, affects firms’ demand for new directors. Whether the labor market rewards a shareholder-friendly or management-friendly reputation is endogenous and depends on aggregate governance. We show that directors’ desire to be invited to other boards creates strategic complementarity of corporate governance across firms. Directors’ reputational concerns amplify the governance system: strong systems become stronger and weak become weaker. We derive implications for multiple directorships, transparency, shareholder activism, and board size.

Keywords: board of directors, corporate governance, reputation, externalities, strategic complementarity, transparency

Introduction

Why do corporate boards look the way they are? Are boards structured optimally to maximize shareholder value, and how do board regulations affect their composition? To a large extent, the structure of corporate boards is governed by the labor market for directors. On the demand side, firms decide which directors to invite based on directors’ reputation and on the preferences of those controlling the nomination process. On the supply side, directors seek to develop their reputation in order to gain more board seats and thereby obtain prestige, power, compensation, and access to valuable networks. Thus, directors’ reputation plays an important role, affecting both directors’ actions and the structure of corporate boards (Fama and Jensen (1983)).

A number of recent institutional and regulatory changes to the director selection process have affected the labor market for directors and the value of reputation. Examples include a shift from plurality to majority voting, proxy access proposals, restrictions on the number of directorships, and increased boardroom transparency. These rules and practices also vary substantially across countries. However, the effect of these factors is not well understood, and some of the recent changes are highly debated.

This paper sheds light on these issues by developing a theory of the labor market for directors and studying how directors’ reputational concerns affect board structure, directors’ behavior, and ultimately firm value.

We emphasize that the effect of directors’ reputational concerns is far from obvious. The key to our argument is that directors care about two conflicting types of reputation, and which type of reputation is rewarded more in the labor market depends on the aggregate quality of corporate governance. If governance is strong and boards of other firms protect the interests of their shareholders, then building a reputation for being shareholder-friendly can help in obtaining more directorships. Conversely, if governance is weak and boards of other firms are captured by their managers, who want to maintain power, then having a management-friendly reputation can be more useful in getting additional board seats. The empirical evidence is consistent with the importance of both types of reputation. Some papers, such as Coles and

Hoi (2003) and Fich and Shivdasani (2007), find that directors who demonstrate shareholder-friendly behavior and monitor the management are more likely to gain additional directorships. Others, such as Helland (2006) and Marshall (2011), find that shareholder-friendly actions actually hurt directors’ chances of being invited to other boards.\(^2\)

To study how these conflicting reputational concerns affect directors’ behavior and firm value, we develop a model with three key components. First, being a board member allows a director to affect corporate governance in his firm and thereby change the allocation of control between management and shareholders. Second, directors’ preferences over the allocation of control, that is, whether directors are shareholder-friendly or management-friendly, are the private information of directors. By allocating control to either managers or shareholders, directors can therefore affect the market’s perception of their shareholder-friendliness. Third, the allocation of control in a given firm determines, among other things, which type of directors it is looking for. In particular, firms that are controlled by shareholders (management) have a demand for shareholder-friendly (management-friendly) directors.

In our setting, the aggregate quality of corporate governance, the structure of the board, and, importantly, the type of reputation that directors need to develop to gain more directorships, are all endogenously determined in equilibrium. To the best of our knowledge, this is the first paper in the literature on reputational concerns in which the type of reputation that is rewarded is endogenous.\(^3\)

Our main result shows that directors’ concerns about their reputation in the labor market create strategic complementarity of corporate governance across firms. In particular, stronger governance in one firm leads to stronger governance in other firms, and vice versa.\(^4\) Intuitively, when corporate governance of most other firms in the market is weak, the decision of whom to invite to the boards of these firms is controlled by managers. Thus, to increase their chances of obtaining additional directorships, directors have incentives to build a reputation for being management-friendly. This type of reputation can be established by giving more control to the

\(^2\) Section 5 provides a review of these and other relevant papers in the empirical literature. See also Adams, Hermelin and Weisbach (2010) for a discussion of this reputational trade-off.

\(^3\) See the section “Related literature” for an overview of relevant papers.

\(^4\) In what follows, we use the term “strong corporate governance” for firms in which shareholders have control, and “weak corporate governance” for firms in which the management has control.
managers of their firms and not interfering with their decisions. Conversely, when corporate
governance in most other firms is strong, directors will strengthen corporate governance of
their firms to build a reputation for being shareholder-friendly. Overall, directors’ reputational
concerns in the labor market create corporate governance externalities between firms.

Strategic complementarity of governance across firms implies that there can be multiple equi-
libria, characterized by the aggregate quality of corporate governance. In particular, we show
that when directors’ reputational concerns are sufficiently important, an equilibrium in which
aggregate governance is strong and the labor market rewards directors for being shareholder-
friendly co-exists with a weak governance equilibrium, in which a management-friendly rep-
utation is rewarded. The existence of multiple equilibria implies that countries with similar
legal and institutional characteristics can have very different corporate governance systems.
This result is consistent with Doidge, Karolyi, and Stulz (2007), who find large cross-country
differences in corporate governance, even after controlling for country characteristics such as
economic development, financial development, the rule of law, and the index of shareholder
rights (La Porta, Lopez-de-Silanes, Shleifer, and Vishny (1998)).

Directors’ reputational concerns, which are the driving force of governance externalities in
our model, can be affected by regulations that restrict the number of directorships a person can
hold or that change the value of a given directorship. These regulations vary across countries.
For example, while the US does not limit the number of board seats a single director can hold,
many European and Asian countries impose such a limit, and this limit is different for different
countries.\footnote{See ECGI corporate governance codes at http://www.ecgi.org/codes/all_codes.php and the White Paper
on Corporate Governance in Asia (OECD 2003). Other policies that can affect directors’ reputational concerns
include term limits and age limits on directors, which are imposed in some countries.}

We show that a policy that increases directors’ reputational concerns, such as an
increase in the allowed number of directorships, can be a double-edged sword, whose effect cru-
cially depends on the aggregate quality of corporate governance. Specifically, when directors
become more concerned about their reputation in the labor market, corporate governance be-
comes even stronger in systems with strong governance, where a shareholder-friendly reputation
is rewarded. However, in systems where managers are in control and directors are rewarded for
being management-friendly, stronger reputational concerns weaken corporate governance even
further. In other words, directors’ reputational concerns amplify the existing aggregate level of corporate governance. This result suggests that policies restricting the number of directorships are more likely to be beneficial in countries with weak governance systems.

Our paper has implications with respect to other dimensions of corporate governance. First, due to strategic complementarity, a small regulatory change, such as a marginal increase in the required percentage of independent directors, can have a very significant effect on the aggregate level of corporate governance. Intuitively, when the percentage of independent directors on a board increases, directors find it easier to object the management and promote strong governance. Moreover, the anticipation that other corporate boards will similarly increase their accountability to shareholders increases the relative value of a shareholder-friendly reputation in the labor market. This reinforces directors’ incentives to promote strong governance in their firms and magnifies the initial effect.

Second, we show that increased transparency of board decision-making strengthens corporate governance if aggregate governance is already strong, but weakens governance even further if aggregate governance is weak. For example, the 2004 Securities and Exchange Commission (SEC) disclosure law, which increased transparency by requiring companies to disclose if one of their directors leaves the board due to a disagreement, could have had adverse unintended consequences.\footnote{Prior to the SEC ruling, disclosure was only required if the director leaving the firm requested his resignation letter to be made public. The new ruling requires all such departures to be disclosed in the firm’s 8-K filing within four business days after the event, even if the director did not provide any written correspondence or request that the matter is made public. In China, a somewhat similar 2004 law requires firms to disclose the names of those independent directors who vote in dissent during the meeting (see Jiang, Wan, and Zhao (2012)).} Intuitively, if aggregate governance is weak and a management-friendly reputation is rewarded in the labor market, directors may be more reluctant to oppose the management when they know that their actions will be disclosed to other market participants. Thus, increasing boardroom transparency with the goal of strengthening a weak governance system is likely to achieve the opposite outcome.

Finally, we study the effects of board size and shareholder activism on corporate governance. In particular, we consider how collective decision-making by directors and the ability of shareholders to intervene and exercise control affect the equilibrium. We highlight that due to externalities in the labor market for directors, board size and shareholder activism affect
The model yields new testable predictions for the director labor market and peer effects in corporate governance. These effects operate through directors’ reputational concerns.

While the focus of the paper is on the market for directors, our arguments can be applied to other settings where agents’ decisions affect both their own reputation and the type of reputation that is valued in the labor market. Examples include the CEO’s choice of corporate culture, an employee’s adoption of a new technology, or an academic’s choice of research agenda.\(^7\)

The paper proceeds as follows. The remainder of the section discusses the related literature and the institutional background. Section 1 introduces the model, and Section 2 presents the analysis. Section 3 provides the comparative statics and implications for shareholder welfare. Section 4 discusses the following extensions: the effect of transparency, shareholder activism, multiple directors on the board, a general number of firms, the value of shareholder control, and heterogeneous outside candidates. Section 5 offers testable predictions and describes the related empirical literature. Section 6 concludes. All proofs are delegated to the Appendix.

**Related literature**

Our paper is related to the literature on strategic complementarities in the labor market. In this literature, strategic complementarities arise when both workers and firms make their investment or entry decisions and there are search frictions (e.g., Acemoglu (1996) and Laing, Palivos and Wang (1995)), or when there are increasing returns to scale in either the matching technology (e.g., Diamond (1982)) or the production function (e.g., Benhabib and Farmer (1994)).\(^8\) Our paper contributes to this literature by identifying a novel channel of strategic complementarities in the labor market, which works through the agents’ reputational concerns. In the model, directors’ actions play two roles: in addition to affecting directors’ own reputation, they also affect the type of reputation that is rewarded in the labor market. This dual effect on supply

\(^7\)For example, by promoting an employee-friendly culture in his firm, the CEO both builds a reputation for being employee-friendly and increases his firm’s demand for employee-friendly managers.

\(^8\)Models with strategic complementarities have important applications in many other fields, such as banking crises (Diamond and Dybvig (1983)), currency attacks (Morris and Shin (1998)), technology adoption (Katz and Shapiro (1986)), and aggregate demand spillovers (Murphy, Shleifer, and Vishny (1989)). See Vives (2005) for an overview of games with strategic complementarities.
and demand creates strategic complementarities between firms.

In the literature on reputational concerns, agents distort their decisions to convince the market that their quality is “high” (e.g., Holmstrom (1999)). As in our paper, reputational concerns in these models can lead to strategic interactions between agents. Differently from this literature, our model features two conflicting types of reputation, and the type of reputation that is rewarded in the labor market is endogenously determined in equilibrium. In the context of directors’ reputational concerns, our paper is related to Song and Thakor (2006), Ruiz-Verdu and Singh (2011), and Levit (2012). These papers focus on the effect of reputational concerns on the interaction between the board and the manager in a single firm. In contrast, our paper studies how directors’ reputational concerns affect all firms in the economy and emphasizes the existence of externalities in corporate governance.

The literature has pointed out that governance externalities can arise from competition for managers (Acharya and Volpin (2010), Acharya, Gabarro, and Volpin (2012), and Dicks (2012)), the takeover market (Burkart and Raff (2012)), and the quality of reported earnings (Nielsen (2006) and Cheng (2011)). Our paper identifies a novel channel of governance externalities working through directors’ reputational concerns, and studies its implications for board regulation. To our knowledge, this is the first paper to model the labor market for directors and its effect on equilibrium board structures. Section 5 discusses several empirical predictions that distinguish our mechanism from other potential reasons for governance externalities.

The paper is also related to the literature that studies how the structure of the board affects board decisions. Adams and Ferreira (2007), Harris and Raviv (2008), Chakraborty and Yilmaz (2011), and Levit (2012) examine what the optimal board structure should be, taking into account the trade-off between board independence and effective communication. In our paper, the structure of the board is determined endogenously in equilibrium through the labor market for directors. The endogenous nature of board structure relates our paper to Hermalin and Weisbach (1998), where the manager and the existing board bargain over the degree of

---

9 For example, reputational concerns can create herding behavior (e.g., Scharfstein and Stein (1990) and Zwiebel (1995)). Relatedly, Ordonez (2012) shows that reputational concerns in credit markets lead to strategic complementarities in risk-taking between borrowers. Differently from our paper, strategic complementarities in his model are created by lenders’ learning from aggregate performance.
independence of newly appointed directors. In their paper, it is the manager’s past performance that determines whether more or less independent directors will be hired, while in our paper, these are directors’ decisions over the firm’s corporate governance that determine the demand for new directors. Finally, by analyzing the effect of board size and collective decision-making within the board, we contribute to the literature that studies interactions between individual board members (e.g., Warther (1998), Harris and Raviv (2008), and Malenko (2012)).

Institutional background

In this section, we describe the director election process in public US firms. The election process starts with the incumbent board of directors selecting director nominees to be presented for shareholder approval at the annual meeting. Since 2003, director nominees in NYSE and Nasdaq listed firms must be approved by independent directors. The nominees chosen by the board are included in the proxy statement, which is distributed to shareholders prior to the annual meeting. Generally, it is hard for shareholders to nominate their own candidates for board seats. Shareholders seeking to nominate alternative candidates have to engage in a costly proxy fight, which involves distributing their own proxy materials and soliciting shareholder votes for the dissident nominees. This process is even more costly in firms that have a staggered board, where only a few board members are subject to reelection each year. In such firms, an activist has to spend several years and win a proxy fight at successive shareholder meetings in order to replace the entire board.

In August 2010, the SEC adopted a new rule to facilitate shareholders’ ability to nominate their own candidates. This rule, referred to as “proxy access,” allowed shareholders owning at least 3% of the shares for at least three prior years to include their nominees in the firm’s proxy statement, instead of distributing their own proxy materials. However, the proxy access rule was immediately challenged in court by the business groups, and in 2011, the court invalidated the rule. Since then, an increasing number of shareholder proposals demanding proxy access have been submitted to companies for inclusion in their proxy statements.

The election process in other countries has some differences. For example, in some European countries, shareholders owning a substantial share percentage have the right to put nominees on the ballot, and majority voting is the default rule in director elections.
Shareholder voting rules can further prevent shareholders from exercising control over the election of the board. For example, many firms use the plurality voting system, under which the nominees who receive the highest number of affirmative votes are elected irrespective of how small the number of affirmative votes actually is. Theoretically, a director could be elected even with a single affirmative vote. In recent years, facing shareholder pressure, many firms have switched to the majority voting system, under which a director has to receive a majority of the votes cast to be elected. A director receiving less than a majority of the votes has to tender his resignation to the board for its consideration.

Overall, the extent of shareholder control over director elections depends on a number of corporate governance characteristics, which vary across firms. First, it depends on the manager’s power over the board: the more influential the manager is, the more likely are independent directors to recommend the candidates supported by the manager. It also depends on how easy it is for shareholders to nominate their own candidates, which, in turn, depends on whether the board is staggered, whether the firm has granted proxy access to large shareholders, and whether shareholders are allowed to call special meetings. Finally, the extent of shareholder control depends on whether the firm has adopted a majority voting system in director elections.

1 Setup

There are two identical firms in the economy, and the board of each firm consists of one director. The game has two stages - the allocation of control stage, followed by the director labor market stage.

At the first stage, each director decides whether to exert effort to transfer control of the firm from the manager (who has control by default) to the shareholders. For example, the director can push for the separation of the CEO and board chairman positions, for a higher proportion of independent directors on the board, or for board declassification. Other shareholder-friendly actions include adopting majority voting for director elections, providing proxy access to share-

\[11\text{In Sections 4.3 and 4.4, respectively, we analyze how the number of directors on the board and the number of firms affect the equilibrium. In unreported analysis, we analyze the case of asymmetric firms and obtain similar results.}\]
holders, and implementing nonbinding shareholder proposals.

The effort decisions are binary and are made simultaneously by the directors. Let $e_i \in \{0, 1\}$ be the effort decision of director in firm $i$ and let $\chi_i \in \{0, 1\}$ be the variable that captures who has control of the firm. Here $\chi_i = 1$ stands for shareholder control in firm $i$, and $\chi_i = 0$ stands for management control. If the director exerts effort, the shareholders of firm $i$ get control for sure. Otherwise, the manager of firm $i$ maintains control. Thus, $\chi_i = e_i$. The allocation of control $\chi = (\chi_i, \chi_j)$, and hence directors’ effort decisions as well, are publicly observable.\footnote{In Section 4.1, we analyze an extension in which the director’s effort decision does not uniquely determine the allocation of control. In this context, we study how the transparency of directors’ effort decisions affects the equilibrium. In Section 4.2, we consider an extension in which an activist shareholder can intervene and affect the allocation of control in the firm.}

We assume that directors differ in their shareholder-friendliness. A shareholder-friendly director has a higher relative benefit from transferring control to shareholders than a management-friendly director. In particular, the type of the director of firm $i$ is $\theta_i$, where $\theta_i$ is distributed according to a continuous distribution function $F$ with mean $\mathbb{E}[\theta]$, median $\mu$, bounded density, and full support on $\mathbb{R}$. The direct utility of a director of type $\theta_i$ from the allocation of control in firm $i$ is $v(\chi_i, \theta_i)$, and his cost of transferring control from the manager to the shareholders is $c(\theta_i) \in \mathbb{R}$. Certain directors can have lower costs of effort compared to others due to higher expertise or lower aversion to confrontation. Alternatively, directors can differ in their direct utility from the allocation of control due to different objectives or differences in opinion. In Section 1.1, we discuss in detail different interpretations of directors’ types.

It is useful to define the net relative benefit from transferring control to shareholders:

$$\Delta(\theta) \equiv v(1, \theta) - v(0, \theta) - c(\theta).$$

We assume that $\Delta(\theta)$ is continuously differentiable and satisfies $\frac{\partial \Delta(\theta)}{\partial \theta} > 0$, $\lim_{\theta \to -\infty} \Delta(\theta) = -\infty$, and $\lim_{\theta \to \infty} \Delta(\theta) = \infty$. This implies that the relative net benefit from transferring control to shareholders is increasing in the director’s type $\theta$. Hence, high $\theta_i$ stands for shareholder-friendliness and low $\theta_i$ stands for management-friendliness. Types are independent across directors, and the type of each director is the director’s private information.

At the second stage, each director can be hit by a shock, in which case he resigns from his...
firm and his firm has to appoint a new director. For example, directors may have to resign due to health issues, family reasons, retirement, or because they have been appointed to an executive position. In particular, let $\xi_i \in \{0, 1\}$ be a random variable with $\Pr[\xi_i = 1] = \lambda$. If $\xi_i = 1$, director of firm $i$ resigns from the board and no longer participates in the labor market for directors. Let $u_{\text{resign}}$ be the director’s utility upon resignation. If $\xi_i = 0$, the director remains on the board of firm $i$ and can also be appointed to the board of firm $j$ if that firm needs a new director. The shocks $\xi_i$ are independent from the allocations of control $\chi_i$, from directors’ types $\theta_i$, and are independent across firms.

If a director resigns, his firm searches for a new director. The firm can hire either the director of its peer firm if that director was not hit by a resignation shock, or an outside candidate, who is not serving on any board. We assume that the type of outside candidates is unknown and its expected value equals $\mathbb{E}[\theta]$, the prior.

While the allocation of control in firm $i$ does not affect whether or not the firm needs a new director, it does affect who makes the director appointment decision. Specifically, if the manager has control ($\chi_i = 0$), then the manager makes the appointment decision, and if shareholders have control ($\chi_i = 1$), then shareholders make the appointment decision. We assume that shareholders have a preference for more shareholder-friendly directors and the manager has a preference for more management-friendly directors. In particular, if $\theta_{i,\text{new}} \in \mathbb{R}$ is the type of the director that firm $i$ hires, then the additional payoff of the shareholders (the manager) of firm $i$ is increasing (decreasing) in $\theta_{i,\text{new}}$. In other words, we assume that the only factor that matters for the controlling party is the new director’s shareholder-friendliness. We deliberately abstract from the effect of other relevant factors, such as directors’ experience and expertise, to emphasize the main intuition of our model.

Let $\pi_i$ denote the reputation of director $i$, defined as the expected type of the director at the beginning of the second stage conditional on all available information. The director’s reputation will be endogenously determined by his effort strategy $e_i(\theta_i)$ and allocation of control $\chi_i$. Directors’ reputation will, in turn, determine firms’ hiring decisions. Denote by $h_i(\chi_i, \pi_j): \{0, 1\} \times \mathbb{R} \to \{0, 1\}$ the hiring decision of firm $i$ based on the allocation of control $\chi_i$, reputation $\pi_j$ of director $j$, and given that director $i$ has resigned ($\xi_i = 1$). In particular, if the firm hires
the outside candidate, then \( h_i = 0 \), and if it hires the director of firm \( j \), then \( h_i = 1 \).

The director gets an additional utility \( \alpha > 0 \) if he is hired by another firm. Parameter \( \alpha \) measures the strength of directors’ reputational concerns. While directors’ financial compensation is likely to be affected by the demand and supply of directors in the labor market, a large component of directors’ utility from board seats is non-pecuniary. Indeed, when asked about their personal benefits from serving on the board, directors list prestige, valuable connections, power, and the opportunity to learn and develop new areas of expertise as being more important than financial compensation (see, for example, director surveys by Lorsch and MacIver (1989) and Burke (1997)). For this reason, and for simplicity, we abstract from the effects of the labor market on \( \alpha \) and take it as a given parameter. In the Supplementary Appendix, we analyze a setup in which a director’s utility from an additional board seat depends on his type and the type of the firm he is invited to. We show that our results are robust to this assumption.

Since a director can only be hired by the other firm if he is not hit by a resignation shock but the other director is, the utility of director \( i \) is given by

\[
\begin{align*}
    u_i &= v\left(x_i, \theta_i\right) - c\left(\theta_i\right) e_i + \alpha \xi_j \left(1 - \xi_i\right) h_j \left(x_j, \pi_i\right) + \xi_i u_{\text{resign}}. \\
\end{align*}
\]

(1)

All agents are risk neutral, and preferences are common knowledge.

1.1 Discussion: Directors’ types

A key assumption of the model is that directors differ in the degree of their shareholder-friendliness. In particular, \( \Delta \), the relative net benefit from transferring control to shareholders, varies across directors and is persistent across firms for a given director. In this section, we discuss several interpretations of shareholder-friendliness.

One reason why some directors are more shareholder-friendly than others is that they are more effective monitors, that is, their costs of promoting strong governance, \( c\left(\theta\right) \), are lower. There are several interpretations of these costs. First, the costs can represent directors’ personality traits. Directors who are more averse to confrontation and boardroom conflict are less likely to challenge the manager since it will inevitably lead to tension in the boardroom.
Second, higher costs of effort could reflect a director’s lack of knowledge and experience of how to evaluate and monitor the CEO. Incapable directors will have to invest more time and effort to be effective when confronting the manager. Finally, the costs of effort can represent the difference between the director’s punishment from the manager for opposing him and the director’s punishment from the shareholders for not monitoring the manager. This interpretation suggests that the costs of effort can in fact be negative (which is allowed in the model).

Another reason why directors can differ in their shareholder-friendliness is that they can have different direct utility from the allocation of control, \( v(\chi, \theta) \). First, directors can disagree on the objective of the board. There is a long-standing debate between corporate governance experts on what the objective of the board should be.\(^{13}\) Some argue that the board is the agent of shareholders and as such has the duty to promote shareholder value by allocating control to them. Others argue that the board represents the corporation as a whole, including employees, management, creditors, customers, and suppliers. According to this view, the board has the duty to promote the value of all stakeholders by allocating control to the management. Under this interpretation, directors with a high \( \theta \) feel strongly about promoting shareholder value, and directors with a low \( \theta \) feel strongly about promoting stakeholder value.

Even if directors agree on the objective of the board, whether it is to maximize shareholders’ or all stakeholders’ value, they can disagree on how to achieve this objective. For example, even if directors agree on shareholder value maximization, some directors may believe that shareholders’ interests are best served by giving control to shareholders, while others may believe that the best way to enhance shareholder value is to give control to the manager. This could be because the success of the firm depends on managerial initiative and firm specific investments that the manager has incentives to take only if he has control (e.g., Grossman and Hart (1986) and Hart and Moore (1990)). Alternatively, this could be because the manager has expertise and private information that he will not communicate to the board unless he has control (e.g., Adams and Ferreira (2007) and Harris and Raviv (2008)). Either way, directors can fundamentally disagree on how to enhance shareholder value, and high \( \theta \) would correspond

to the belief that shareholder control is the most efficient way to achieve this objective. In Section 4.5, we build on this interpretation and analyze the case in which the relative value from shareholder control can differ across firms.

Regardless of the interpretation, both the cost of effort and the utility from the allocation of control depend on directors’ personalities, backgrounds, and beliefs, and can therefore vary substantially across directors and not be easily observable by outsiders. At least to some extent, these characteristics are director-specific. In our analysis, we do not take a stand on what the most relevant interpretation is and think of a director’s type $\theta$ as aggregating these different characteristics. The assumptions on the functional form of $\Delta(\theta)$ capture the above interpretations in a reduced form way.

2 Analysis

The solution concept is the Perfect Bayesian Equilibrium (PBE), which is characterized by directors’ effort decisions $e_i^*(\theta_i)$, $e_j^*(\theta_j)$, beliefs about the type of directors $\pi_i^*(\chi_i)$, and firms’ hiring decisions $h_i^*(\chi_i, \pi_j)$. A formal definition of a PBE is provided in the Appendix.

Let $\tau_j$ denote the ex-ante probability that shareholders of firm $j$ obtain control. Then $\tau_j$ is determined by the effort strategy $e_j(\theta_j)$ and is given by

$$\tau_j = \Pr [\theta \in \{\theta : e_j(\theta) = 1\}] .$$

Let $\pi_i^*(\chi_i) \equiv \mathbb{E}[\theta|\chi_i]$ be the equilibrium inference about the type of director $i$ upon outcome $\chi_i$. Consider director $i$’s utility from having a reputation $\pi_i$. If $\chi_j = 1$, i.e., if shareholders of firm $j$ get control, then firm $j$ will hire director $i$ if and only if his reputation is above the

---

$^{14}$Similarly, directors can agree on stakeholder value maximization but disagree on how to achieve this objective. For example, some directors may believe that since shareholders are the residual claimants on the firm’s assets, allocating control to shareholders will guarantee that the value of all stakeholders is maximized. Other directors may be concerned that shareholders are myopic and can thus take advantage of other stakeholders to make a short-run profit. These directors will prefer to give more control to the management.

$^{15}$It is not necessary for our results that $\theta_i$ is perfectly transferable across firms. As long as there is some level of persistence, the results continue to hold. Consistent with the assumption that $\theta_i$ is transferable across firms, Bouwman (2011) finds that a firm’s governance practices move in the direction of governance practices of the other firms its directors serve at.
reputation of the outside candidate $\mathbb{E} [\theta]$. Similarly, if $\chi_j = 0$, i.e., the manager of firm $j$ retains control, then firm $j$ will hire director $i$ if and only if his reputation is below the reputation of the outside candidate.\(^{16}\) In other words, $h_j (1, \pi_i) = 1$ if and only if $\pi_i \geq \mathbb{E} [\theta]$, and $h_j (0, \pi_i) = 1$ if and only if $\pi_i < \mathbb{E} [\theta]$. Given that, the expected direct benefit of director $i$ from obtaining reputation $\pi_i$ is given by $\alpha \lambda (1 - \lambda) \Lambda (\pi_i, \tau_j)$, where

$$\Lambda (\pi, \tau) = \tau \cdot 1 \{ \pi \geq \mathbb{E} [\theta] \} + (1 - \tau) \cdot 1 \{ \pi < \mathbb{E} [\theta] \}. \quad (3)$$

Note that for any $\underline{\pi}, \overline{\pi}$ such that $\overline{\pi} \geq \mathbb{E} [\theta] > \underline{\pi}$, $\Lambda (\overline{\pi}, \tau) > \Lambda (\underline{\pi}, \tau)$ if and only if $\tau > 0.5$.

Intuitively, whether a director wants to have a shareholder-friendly or a management-friendly reputation depends on the allocation of control in other firms. If managers (shareholders) are the main decision-makers in other firms, i.e., $\tau$ is small (large), then the director is more likely to be invited to other boards if he is known for being management-friendly (shareholder-friendly).

Another property of $\Lambda (\pi, \tau)$ is that a director benefits from there being more shareholder-controlled firms ($\frac{\partial \Lambda}{\partial \tau} > 0$) if and only if he has a shareholder-friendly reputation ($\pi \geq \mathbb{E} [\theta]$).

Let $U_i (e_i, \theta_i)$ be the expected utility of director $i$ given his type $\theta_i$ and effort $e_i$, and taking as given beliefs $\pi^*_i (\cdot)$ and the probability of shareholder control in the other firm $\tau_j = \tau_j (e_j (\cdot))$. Then $U_i (e_i, \theta_i)$ is given by

$$U_i (e_i, \theta_i) = v (e_i, \theta_i) - c (\theta_i) e_i + \alpha \lambda (1 - \lambda) \Lambda (\pi^*_i (e_i), \tau_j) + \lambda u_{\text{resign}}. \quad (4)$$

Using (4), the following lemma shows that in any equilibrium, the director follows a threshold strategy and exerts effort only if his preference for shareholder control is sufficiently strong.\(^{17}\)

**Lemma 1** In any equilibrium, there exists $\theta^*_i$ such that $e_i (\theta_i) = 1$ if and only if $\theta_i > \theta^*_i$.

\(^{16}\)Without loss of generality, we assume that if a director’s reputation equals $\mathbb{E} [\theta]$, then shareholders will hire the director, and the manager will hire the outside candidate.

\(^{17}\)In this sense, all equilibria of the game are semi-pooling: all types above (below) the threshold follow the same strategy, but types above the threshold follow a different strategy than types below the threshold. This result is due to the assumption that $\Delta (\cdot)$ is unbounded. If $\Delta (\cdot)$ were bounded, there could also exist pooling equilibria, in which all types follow the same strategy of exerting (or not exerting) effort, i.e., the threshold $\theta^*_i$ in Lemma 1 could be infinite. Since our results would continue to hold in this setting as well, we make the assumption that $\Delta (\cdot)$ is unbounded for simplicity.
Given Lemma 1 and the properties of conditional expectations, it follows that

$$\pi^*_i(0) = \mathbb{E}[\theta|\theta \leq \theta^*_i] < \mathbb{E}[\theta] < \mathbb{E}[\theta|\theta > \theta^*_i] = \pi^*_i(1)$$ \hspace{1cm} (5)

and

$$\tau^*_j = \text{Pr}[\theta > \theta^*_j] = 1 - F(\theta^*_j).$$ \hspace{1cm} (6)

Consider the best response function $\beta_i(\theta_j)$ of director $i$, taking as given that director $j$ exerts effort when his type exceeds the threshold $\theta_j$. The best response function defines the threshold $\beta_i(\theta_j)$ such that types $\theta_i > \beta_i(\theta_j)$ exert effort. From (4) and the proof of Lemma 1, it follows that $\beta_i(\theta_j) = \beta(\theta_j)$, where

$$\beta(\theta) = \Delta^{-1}(\alpha \lambda (1 - \lambda)(2F(\theta) - 1)).$$ \hspace{1cm} (7)

Since $\Delta(\theta)$ is strictly increasing, continuous, and takes all values on $(-\infty, +\infty)$, its inverse $\Delta^{-1}(\cdot)$ is a well defined, strictly increasing, and continuous function. Note that $\beta_i(\theta) = \beta_j(\theta)$, i.e., the directors’ best response functions are identical. Note also that $\beta(\theta)$ strictly increases in $\theta$ and takes all values in the interval $[\Delta^{-1}(-\alpha \lambda (1 - \lambda)), \Delta^{-1}(\alpha \lambda (1 - \lambda))]$.

Since the best response threshold of a director is increasing in the threshold of his peer, the game exhibits strategic complementarity. Intuitively, if the director of firm $j$ is more likely to exert effort ($\theta_j$ decreases), then shareholders of firm $j$ are more likely to get control and have the power to appoint directors to their board. Therefore, director $i$’s relative reward for having a shareholder-friendly reputation is higher. This effect increases the incentives of director $i$ to exert effort, decreasing the threshold $\theta^*_i$.

The following lemma characterizes the set of equilibria of the model using the properties of $\beta(\theta)$ and the symmetry of the best response functions.

**Lemma 2** An equilibrium always exists, and any equilibrium is symmetric.

Since all equilibria of the game are symmetric, i.e., $\theta^*_i = \theta^*_j = \theta^*$, any equilibrium $\theta^*$ is the
solution of \( \beta(\theta^*) = \theta^* \). Define \( \tau_j^* = \tau_i^* = 1 - F(\theta^*) \) by \( \tau^* \), \( \pi_i^*(1) = \pi_j^*(1) \) by \( \pi^*(1) \), and \( \pi_i^*(0) = \pi_j^*(0) \) by \( \pi^*(0) \). Given (5) and the properties of \( \Gamma(\pi, \tau) \) discussed above, \( \Gamma(\pi^*(1), \tau^*) > \Gamma(\pi^*(0), \tau^*) \) if and only if \( \tau^* > 0.5 \) or, equivalently, \( \theta^* < \mu \). In other words, a shareholder-friendly reputation generates a higher payoff than a management-friendly reputation if and only if there is a higher than 50% chance that the other firm will be controlled by shareholders. Based on this argument, the next definition classifies potential equilibria into two types.

**Definition 1** An equilibrium is called shareholder-friendly if \( \tau^* > 0.5 \) and is called management-friendly if \( \tau^* < 0.5 \).

Due to strategic complementarity, our model can have multiple equilibria. Moreover, the next proposition shows that when reputational concerns are sufficiently important, there always exist at least one shareholder-friendly and at least one management-friendly equilibrium. Thus, equilibria with strong and weak governance can co-exist for a given set of parameters, suggesting that countries or industries with similar characteristics can have different corporate governance systems as an equilibrium outcome.

**Proposition 1** There exist \( \bar{\alpha} \) and \( \alpha \), \( \bar{\alpha} \geq \alpha > 0 \), such that:

(i) If \( \alpha > \bar{\alpha} \), there exist at least one shareholder-friendly equilibrium and at least one management-friendly equilibrium.

(ii) If \( \alpha < \bar{\alpha} \), all equilibria are of the same type. In particular, all equilibria are management-friendly if \( \Delta(\mu) < 0 \) and shareholder-friendly if \( \Delta(\mu) > 0 \).

(iii) If \( \alpha < \bar{\alpha} \), the equilibrium is unique.

The intuition behind Proposition 1 is as follows. In our model, strategic complementarity between firms’ corporate governance decisions arises due to directors’ reputational concerns, represented by parameter \( \alpha \). When \( \alpha \) increases, reputation becomes more important for directors, and the complementarity in their decisions becomes stronger. For this reason, multiple
equilibria are more likely to exist when reputational concerns are significant. Figure 1 illustrates this effect by plotting the best response function of directors for $c(\theta) = 2.75$, $\lambda = 0.5$, a standard normal distribution of types, and the utility function $v(\chi, \theta) = (\theta + 1)\chi$.

![Figure 1: Best response function $\beta(\theta)$ for $c(\theta) = 2.75$, $\lambda = 0.5$, $v(\chi, \theta) = (\theta + 1)\chi$, and standard normal $F$](image)

First, when $\alpha = 0$, directors do not care about additional board seats and hence make their effort decisions independently of other directors’ strategies. Hence, the best response function $\beta(\theta)$ for $\alpha = 0$ is a constant function with value $\Delta^{-1}(0)$. Therefore, a unique equilibrium exists, and this equilibrium is management-friendly since directors’ cost of effort $c(\theta) = 2.75$ is sufficiently large relative to $\mu = 0$. When $\alpha$ becomes positive, strategic complementarity arises, and the best response function $\beta(\theta)$ becomes strictly increasing. The dashed line in Figure 1 represents $\beta(\theta)$ for $\alpha = 2$. Although $\beta(\theta)$ is increasing, externalities between firms are not strong enough, and hence the game still has a unique, management-friendly, equilibrium ($\theta^*$ around 2.24, which corresponds to $\tau^*$ around 0.01). However, as Proposition 1 shows, when $\alpha$ increases further, strong externalities between firms give rise to multiple equilibria, some of which are shareholder-friendly. In particular, when $\alpha = 20$ (the bold line in Figure 1), the graph of the best response function crosses the 45-degree line in three points, corresponding to the three equilibria of the game. Two of them ($\theta^*$ around -3.25 and -0.64) are shareholder-friendly, and the third one ($\theta^*$ around 6.75) is management-friendly.

When multiple equilibria exist, some of them can be unstable. In what follows, we define stability and classify equilibria accordingly. The definition is based on local tatonnement sta-
bility, which requires that a dynamic adjustment process, in which directors take turns playing a best response to each others’ current strategies, converges to the equilibrium from any strategy pair in the neighborhood of the equilibrium. Before introducing the formal definition of stability, we make the following assumption for the remainder of the paper.

Assumption 1 $\Delta (\mu) \neq 0$.

As the proof of Proposition 2 shows, this assumption ensures that for almost all $\alpha \in \mathbb{R}$, $\frac{\partial \beta(\theta)}{\partial \theta} \bigg|_{\theta=\theta^*} \neq 1$ in any equilibrium $\theta^*$. In other words, whenever the best response function and the 45-degree line intersect, they are not tangent to each other. This assumption guarantees the existence of stable equilibria and is essentially a regularity condition. Under this assumption, local tatônnement stability is equivalent to the following definition.

**Definition 2** An equilibrium $\theta^*$ is called “stable” if $\frac{\partial \beta(\theta)}{\partial \theta} \bigg|_{\theta=\theta^*} < 1$.

Thus, stability requires that the best response function of director $i$ to the strategy of director $j$ crosses the 45-degree line from above.

**Proposition 2** A stable equilibrium exists for almost all $\alpha \in \mathbb{R}$.

Proposition 2 implies that if an equilibrium is unique, then it is stable. For example, the case $\alpha = 2$ in Figure 1 corresponds to a unique stable equilibrium. The case $\alpha = 20$ features three equilibria. The two boundary equilibria are stable, and the interior equilibrium is unstable.$^{18}$

### 3 Shareholder welfare and comparative statics

In our setting, shareholder welfare can be measured by the equilibrium quality of corporate governance, defined as the probability that shareholders get control: $\tau^* = 1 - F(\theta^*)$. For example, one can think of shareholders of firm $i$ as being infinitely shareholder-friendly ($\theta = \infty$).

---

$^{18}$In the proof of Proposition 1, we show that all statements of the proposition are valid for stable equilibria.
and getting utility \( v(\chi_i, +\infty) \) from the allocation of control \( \chi_i \). Hence, all equilibria can be ranked by shareholder welfare, where equilibria with a lower \( \theta^* \) correspond to greater shareholder welfare. Since the best response function \( \beta(\cdot) \) is bounded and increasing, by Tarski’s Fixed Point Theorem, \( \beta(\cdot) \) has the least and the greatest fixed points (equilibria). We denote these two equilibria by \( \theta^* \) and \( \bar{\theta}^* \) respectively and call them “the most shareholder-friendly” and “the least shareholder-friendly” equilibria of the game.\(^1\)

Generally, as discussed in Section 1.1, allocating control to shareholders might not be the most effective way to maximize shareholder welfare. Managerial initiative and firm-specific investments, as well as efficient communication between the manager and the board, which are important for good performance, may require delegating control to the manager. To incorporate this possibility, in Section 4.5, we analyze an extension in which the optimal allocation of control between the manager and shareholders can differ across firms.

In the remainder of this section, we study the comparative statics of the equilibrium probability of shareholder control. We focus on local comparative statics, when the equilibrium continues to exist upon a small change of parameters. All stable equilibria have this property.

**Proposition 3** Consider any stable equilibrium. Then:

(i) \( \tau^* \) decreases with \( c \).\(^2\)

(ii) If \( F(\kappa_2, \cdot) \) first-order stochastically dominates \( F(\kappa_1, \cdot) \) for \( \kappa_2 > \kappa_1 \), \( \tau^* \) increases with \( \kappa \).

(iii) \( \tau^* \) increases with \( \alpha \) if and only if the equilibrium is shareholder-friendly.

(iv) If the distribution of types is symmetric and \( F(\sigma_2, \cdot) \) is more risky than \( F(\sigma_1, \cdot) \) for \( \sigma_2 > \sigma_1 \) in the sense of a simple mean-preserving spread, then \( \tau^* \) increases with \( \sigma \) if and only if the equilibrium is management-friendly.

---

\(^1\)Note that “the most shareholder-friendly” equilibrium can be management-friendly if all equilibria of the game are management-friendly, and vice versa.

\(^2\)In the subsequent discussion, we refer to changes in \( c \) as a uniform shift of \( c(\theta) \). In other words, we analyze the comparative statics with respect to a parameter \( c \) such that \( c(\theta) = c + c_0(\theta) \) for some function \( c_0(\cdot) \).
These comparative statics results only hold in stable equilibria. Indeed, the proof of Proposition 3 is based on the fact that for any parameter $p$,
\[
\frac{\partial \theta^*}{\partial p} = M(\theta^*) \times \frac{\partial \beta(\theta)}{\partial p}|_{\theta=\theta^*},
\]
where the multiplier
\[
M(\theta^*) \equiv \frac{1}{1 - \frac{\partial \beta(\theta)}{\partial c}|_{\theta=\theta^*}}
\]
is strictly positive in any stable equilibrium. The same logic implies the opposite comparative statics in non-stable equilibria, in which $\frac{\partial \beta(\theta)}{\partial c}|_{\theta=\theta^*} > 1$. This result is standard in the literature on games with strategic complementarities (see, for example, Vives (2005)).

Note also that since $\frac{\partial \beta(\theta)}{\partial c}|_{\theta=\theta^*} > 0$, the multiplier $M(\theta^*)$ is strictly greater than one in any stable equilibrium. Hence, small changes in parameters are amplified due to strategic complementarity of directors’ effort decisions. To see the intuition, consider a uniform decrease in directors’ cost of effort by $c$, for example, due to a new regulation. The direct effect of this change on a director’s incentives to exert effort is represented by the term $\frac{\partial \beta(\theta)}{\partial c}$). However, since the director in the other firm is also more likely to exert effort, the other firm is now more likely to be controlled by shareholders. This second, indirect, effect increases the value of a shareholder-friendly reputation in the labor market and magnifies the director’s incentives to exert effort. In the extreme case, when $\frac{\partial \beta(\theta)}{\partial c}|_{\theta=\theta^*} \to 1$, then $M(\theta^*) \to \infty$. This means that due to strategic complementarity, even a very small shock to the parameters of the model has a very significant effect on the equilibrium outcome.

The intuition for the comparative statics of $\kappa$ is similar to the one of $c$. Note, however, that a higher likelihood of shareholder-friendly directors (higher $\kappa$) leads to a higher probability of shareholder control for two reasons. First, keeping directors’ threshold strategy $\theta^*$ fixed, it is more likely that each individual director’s type will be above the threshold. This effect is amplified by the decrease in directors’ equilibrium threshold $\theta^*$: knowing that the other firm is now more likely to be controlled by shareholders, each director has stronger incentives to exert effort and thereby build a shareholder-friendly reputation.

The third statement of Proposition 3 shows that directors’ reputational concerns ($\alpha$) increase
the probability of shareholder control only if the equilibrium is shareholder-friendly ($\tau^* > 0.5$). This is because in a management-friendly equilibrium, managers of other firms, rather than shareholders, make the appointment decisions, and hence having a shareholder-friendly reputation hurts directors’ chances of being invited to other boards. In this sense, directors’ reputational concerns amplify corporate governance: as $\alpha$ increases, strong governance systems become stronger and weak systems become weaker. This suggests that a regulation that increases the value of reputation in the director labor market (e.g., increasing the allowed number of directorships a person can hold) strengthens corporate governance only if the existing quality of corporate governance is sufficiently strong.

Parameter $\sigma$ captures the uncertainty about directors’ types. For example, it reflects the quality of firms’ disclosure about directors’ education, employment, and prior history. The proposition shows that an increase in the uncertainty about directors’ types attenuates the effect of reputational concerns on corporate governance: strong systems become weaker and vice versa. The reason is that higher uncertainty about the other director’s type makes it harder for a director to predict whether the other firm will be controlled by managers or by shareholders. If the equilibrium is shareholder-friendly, this increased uncertainty decreases the director’s relative reward for creating a shareholder-friendly reputation and thus reduces his incentives to exert effort. The opposite is true in a management-friendly equilibrium.

4 Extensions

In this section, we discuss several extensions of the basic model. The formal setups, results, and proofs for these extensions are provided in the Supplementary Appendix.

4.1 Transparency

While the board’s decision-making process is generally opaque, some recent regulations have increased boardroom transparency. For example, as discussed in the introduction, the 2004 SEC law requires firms to disclose any director departure that is due to a disagreement, and the 2004 law in China requires firms to disclose the names of directors who vote in dissent. Our
setting allows us to study whether increased transparency of board decision-making is beneficial for corporate governance.

To study the effect of transparency, we extend the basic model and assume that if a director exerts effort, shareholders get control only with some probability. Hence, the director’s effort decision cannot be directly inferred from the publicly observable allocation of control. The extent to which the director’s decision is observable depends on the degree of transparency. Specifically, the director’s effort is publicly revealed prior to the second stage with probability η, which is a measure of transparency. Other assumptions of the model are unchanged.

We show that higher transparency increases the probability of shareholder control if and only if the equilibrium is shareholder-friendly. Intuitively, when directors’ behavior is more likely to be publicly observed, they are more eager to take shareholder-friendly actions only if a shareholder-friendly reputation is rewarded in the market. Thus, the effect of regulations increasing boardroom transparency crucially depends on the aggregate corporate governance.

### 4.2 Shareholder activism

In practice, the allocation of control in the firm can be affected not only by its directors, but also by its shareholders. Activist investors can intervene if they are concerned that the board will not be monitoring the manager effectively. For example, an activist can launch a proxy fight and place its representatives on the board, ensuring that some directors will always take shareholder-friendly actions. To incorporate this possibility, we augment the basic model with an additional stage of shareholder activism before directors’ effort decisions. In each firm, there is an activist investor who can incur a cost to intervene and transfer control to shareholders. If the activist does not intervene, the allocation of control is determined by directors’ decisions, as in the basic model. The activists’ intervention decisions are publicly observable and made simultaneously. Their costs of intervention are their private information.

In equilibrium, each activist intervenes if and only if her cost does not exceed a certain threshold. Shareholder activism acts as a substitute for board monitoring: the activist is more likely to intervene when directors’ effort to improve governance is lower. The comparative statics of the extended model is similar to that in the basic model. Specifically, an increase in
always decreases (increases) shareholder welfare net of intervention costs, while the effect of directors’ reputational concerns depends on whether the system is in a shareholder-friendly or in a management-friendly equilibrium.

Interestingly, we show that there are externalities in shareholder activism across firms. In particular, the activists’ intervention decisions are strategic substitutes: a higher probability of intervention in one firm leads to a lower probability of intervention in the other firm. The intuition is the following. If the activist in firm $j$ is more likely to intervene and transfer control to shareholders, firm $j$ is more likely to have a demand for shareholder-friendly directors. Hence, the director of firm $i$ has stronger incentives to establish a shareholder-friendly reputation and thus is more likely to transfer control to shareholders in his firm. This implies that shareholder activism in firm $i$ is needed less. Note that strategic substitutability of activists’ intervention decisions is due to directors’ reputational concerns and is not present when $\alpha = 0$.

4.3 Board size

Corporate boards typically consist of multiple directors and operate by collective decision-making. We therefore extend the model and assume that each board consists of $K \geq 2$ directors. The board’s decision-making process is modeled as follows. All directors simultaneously decide whether to exert effort. If at least $T \in \{1, \ldots, K\}$ directors exert effort (e.g., vote for a proposal that restricts the manager’s power), then shareholders obtain control. Otherwise, the management retains control. Individual effort decisions are not observable, but the allocation of control in each firm is observable and thus affects directors’ reputation. At the second stage, we abstract from the mechanical effect of board size on the supply and demand for directors in order to focus on the effect of board size on collective decision-making.\footnote{Specifically, we assume that at the second stage, with probability $\lambda K$, exactly one director in each firm is hit by a resignation shock. Each of $K$ directors has an equal chance of being hit by the shock. We also assume that if several directors have the same reputation, they are equally likely to be invited to the other board. In this case, conditional on $\chi_i = \chi_j$, the probability that a given director of firm $i$ is invited to board $j$ equals $\lambda$ for any $K$, which allows us to abstract from the effect of $K$ on the supply and demand for directors.}

Generally, a director’s actions are affected both by the board size and voting rule of his own firm (due to free-riding among directors) and by the board size and voting rule of the
other firm (due to externalities in the labor market). Since the focus of our paper is on externalities between firms, we shut down the free-riding channel by assuming that directors’ effort is costless. When effort is costless, the only reason why board size affects directors’ behavior is due to externalities between firms.

We show that the extended model exhibits strategic complementarity as well. Moreover, the effect of board size on directors’ incentives to promote strong governance depends on the voting rule. For example, if unanimity is required to give control to shareholders \( (T = K) \), a larger board size decreases directors’ incentives to vote for shareholder control. This is because under unanimity, a larger board size at other firms implies that those boards are less likely to transfer control to shareholders, which decreases the value of a shareholder-friendly reputation in the labor market. When the voting rule is a simple majority rule, the effect of board size depends on the aggregate level of corporate governance. Specifically, a larger board size increases directors’ incentives to vote for shareholder control if and only if the equilibrium is shareholder-friendly. Intuitively, under a simple majority rule, the equilibrium is shareholder-friendly (management-friendly) if the probability that each director exerts effort is greater (smaller) than 50% and hence, when the number of directors on the board increases, the likelihood that at least half will exert effort increases (decreases). This result implies that under a simple majority rule, board size amplifies corporate governance in the sense that weak governance systems become weaker and strong governance systems become stronger as board size increases.

4.4 Multiple firms

We also consider the extension of the model to \( N \geq 2 \) firms. As in the basic model, the director of each firm is hit by a resignation shock with probability \( \lambda \), and the shocks are independent across directors. Note that based on the allocation of control across firms after the first stage, the labor market for directors is divided into two segments: firms controlled by shareholders search among directors with a shareholder-friendly reputation, and firms controlled by managers search among directors with a management-friendly reputation. We assume that the labor market allocation is efficient in the following sense. In equilibrium, no firm that is controlled by shareholders (management) hires an outside candidate if a director serving on one of the boards
has a shareholder-friendly (management-friendly) reputation and has the capacity to serve on another board. If such a situation occurred, both the firm and the director would be better off matching with each other. We also assume that if there is excess supply of directors in any segment of the market, all directors in this segment have equal probability of being invited to the boards of other firms. Finally, we assume that directors are not limited in the number of boards on which they can serve.\textsuperscript{22} We focus on symmetric equilibria.

We show that the results of the basic model continue to hold for any number of firms. In particular, for any $N$, the extended model exhibits strategic complementarity as well. Moreover, the comparative statics results of the extended model are similar to those in Proposition 3.\textsuperscript{23}

### 4.5 Value of shareholder control

If managers have high expertise or if they need to be given incentives to make firm-specific investments, shareholders may be better off delegating control to them despite potential conflicts of interest (e.g., Grossman and Hart (1986), Hart and Moore (1990), Adams and Ferreira (2007), Harris and Raviv (2008)). The relative value from management control can differ across firms. To capture this cross-sectional heterogeneity, we extend the model and assume that in each firm, shareholder control is optimal only with probability $\psi \in (0, 1]$. With probability $1 - \psi$, shareholder value is maximized if control is delegated to the manager. The optimal allocation of control in each firm is independent across firms and is privately observed by the firm’s director. We also assume that when management control is optimal, the director’s relative benefit from transferring control to shareholders is negative and is smaller than when shareholder control is optimal, but that it still increases with the director’s shareholder-friendliness.

We show that the extended model exhibits strategic complementarity as well. Importantly,\textsuperscript{22} In practice, the number of board seats that a director can hold could be limited by the director’s time constraints or by regulation (for example, many countries impose a limit on the number of directorships). If there were a limit on the number of directorships, then raising this limit would increase the value of reputation. Since the effect of reputational concerns on directors’ incentives to exert effort depends on whether the equilibrium is shareholder- or management-friendly, the effect of increasing the allowed number of directorships would depend on the nature of equilibrium as well. To see this, note that in a two-firm case, changing $\alpha$ from zero to a positive number is equivalent to increasing the cap on the number of directorships from one to two.

\textsuperscript{23}In unreported analysis, we show that the effect of $N$ on the equilibrium level of corporate governance is non-monotonic and is generally ambiguous. For example, the direction of the effect depends on whether or not $\Delta (\cdot)$ is bounded.
equilibria of this game feature two potential types of inefficiency. The first type of inefficiency is similar to the basic model and arises when directors do not transfer control to shareholders even though shareholder control is optimal. In addition, an equilibrium can feature another type of inefficiency, when directors allocate control to shareholders even though management control is optimal. The only reason why directors do this is to signal their shareholder-friendliness to other firms (which is beneficial if a shareholder-friendly reputation is rewarded). Hence, the second type of inefficiency does not arise if $\alpha = 0$ or if the equilibrium is management-friendly.

We measure shareholder welfare by the ex-ante probability that control is allocated efficiently. When the only source of inefficiency is excessive management control, then, similar to the basic model, a decrease in the costs of effort and an increase in $\kappa$ always increase shareholder welfare, while an increase in directors’ reputational concerns increases shareholder welfare if and only if the equilibrium is shareholder-friendly. However, when the equilibrium features excessive shareholder control as well, the effect of these parameters is ambiguous and depends on $\psi$. For example, shareholder welfare can actually increase with directors’ costs of effort if $\psi$ is small. Intuitively, since directors transfer control to shareholders even when it is inefficient to do so, higher costs of effort serve as a commitment to delegate control to managers, which can benefit shareholders. Since excessive shareholder control arises in shareholder-friendly, but not in manager-friendly equilibria, this result implies that the effect of regulations affecting $c$ or $\kappa$ depends on the aggregate level of corporate governance.

4.6 **Outside candidates**

In the basic model, we assume that the type of outside candidates is unknown and thus their expected type (reputation) is $E[\theta]$. Some outside candidates, however, could have partly revealed the degree of their shareholder-friendliness through their professional activities and hence can have a reputation $\varphi \neq E[\theta]$. For example, CEOs of other firms are a large source of potential outside candidates. Arguably, CEOs are intrinsically more management-friendly because they are managers themselves. In this case, $\varphi_{CEOS} < E[\theta]$. We therefore, consider an extension of the basic model in which the set of potential outside candidates includes both directors with reputation $E[\theta]$ and directors with reputation $\varphi \in \mathbb{R}$.
We show that if the outside candidates are sufficiently shareholder-friendly (management-friendly), corporate governance is actually weaker (stronger) compared to the basic model. To see the intuition, suppose, for example, that \( \varphi \) is relatively high. In this case, a director who obtains a shareholder-friendly reputation by transferring control to shareholders will never be invited to another board. Indeed, a shareholder-controlled firm prefers to hire an outside candidate with reputation \( \varphi \) since he is even more shareholder-friendly than the director. A management-friendly firm prefers to hire an outside candidate with reputation \( \mathbb{E}[\theta] \) since he is more management-friendly than the director. In contrast, a director with a management-friendly reputation will be preferred by management-controlled firms over both types of outside candidates. Thus, compared to the basic model, the relative benefit from creating a shareholder-friendly reputation is lower. This effect reduces directors’ incentives to promote strong corporate governance, and equilibria become less shareholder-friendly.

5 Empirical predictions

In this section, we discuss our paper in the context of the existing empirical literature and offer new testable implications of the analysis.

The premise of our paper is that directors have to trade off two conflicting types of reputation - one for being shareholder-friendly and one for being management-friendly. Consistent with the existence of this trade-off, the literature has found mixed results with respect to whether the labor market rewards directors for imposing discipline on the management. Consistent with the view that a shareholder-friendly reputation is rewarded, a number of papers find that directors are held accountable for failing to monitor the management effectively.\(^\text{24}\) Conversely, consistent with the view that a management-friendly reputation is rewarded, Helland (2006) finds that directors of firms charged with fraud, experience an increase in the number of outside directorships, and Marshall (2011) shows that directors who resign from the board over a

\(^{24}\) Coles and Hoi (2003) show that directors who rejected the Pennsylvania Senate Bill 1310 antitakeover provisions were three times as likely to gain additional directorships than those who retained the provisions. Fich and Shivdasani (2007) find that following a financial fraud lawsuit, directors are likely to lose board seats at other firms, particularly those with strong governance. See also Harford (2003), Yermack (2004), Srinivasan (2005), Ertimur, Ferri, and Stubben (2010), and Jiang, Wan, and Zhao (2012) in the context of Chinese firms.
disagreement, experience a loss in board seats over the five year period following the dispute.\footnote{Relatedly, Ertimur, Ferri, and Maber (2011) find no evidence that directors of firms involved in option backdating incur reputational penalties at other firms.}

Most of the existing literature looks at the aggregate number of board seats gained by directors. In contrast, our paper emphasizes that whether directors’ shareholder-friendly actions will be rewarded in the labor market crucially depends on the balance of power at other firms. Formally, the first implication is the following.

**Prediction 1** *Directors who demonstrate their shareholder-friendliness are more (less) likely to be subsequently appointed to boards of firms with stronger (weaker) corporate governance.*

Shareholder-friendly directors can be identified as those who vote against the management (Jiang, Wan, and Zhao (2012)) or leave the board due to a disagreement (Marshall (2011)). Alternatively, one can look at firms where a director holds a board seat and measure the observable changes in these firms’ corporate governance during the director’s tenure (e.g., removal of antitakeover defenses or CEO-chairman separation).

Zajac and Westphal (1996), Eminet and Guedri (2010), and Bouwman (2011) find evidence consistent with the first prediction. For example, Zajac and Westphal (1996) show that directors on boards that have recently increased the ratio of outside directors, separated the CEO and chairman positions, or decreased executive compensation, have fewer subsequent appointments to firms with low board control but more appointments to firms with high board control.\footnote{Bouwman (2011) shows that a firm is more likely to select an individual as its director if this individual is a director at firms whose governance practices are similar to the firm’s existing governance practices. In the context of French firms, Eminet and Guedri (2010) find that directors who implement governance reforms that increase (decrease) control over management are more likely to be appointed to boards with (without) nominating committees and boards with nominating committees dominated by non-executive (executive) directors.}

The main result of our paper is the existence of corporate governance externalities between firms. While governance externalities between firms can be due to several reasons, the unique feature of our model is that externalities arise due to directors’ reputational concerns in the labor market. Thus, another empirical implication, which helps distinguish our mechanism from other potential mechanisms, is the following.
Prediction 2 A positive exogenous shock to the corporate governance of one firm should positively affect corporate governance of other firms, and this spillover effect should be stronger for firms whose directors have stronger reputational concerns.

Since governance externalities arise through the labor market for directors, they are likely to be stronger across firms in the same segment of the labor market, such as firms in the same geographic area and firms in the same industry. Indeed, the market for directors is somewhat segmented both by geographic location (e.g., Knyazeva, Knyazeva, and Masulis (2012)) and by industry, since firms look for candidates with relevant expertise and industry knowledge (e.g., Kini et al. (2011)). Thus, the empirical predictions of this section are likely to be stronger if a firm’s peer group is defined as firms in related industries or firms in close geographic proximity.

The model also has implications for the effect of directors’ reputational concerns on their incentives to take shareholder-friendly actions. Our analysis emphasizes that the effect of reputational concerns depends on corporate governance at other firms. In particular:

Prediction 3 Directors with stronger reputational concerns are more (less) likely to take shareholder-friendly actions if corporate governance of other firms is stronger (weaker).

While several papers (e.g., Marshall (2011) and Jiang, Wan, and Zhao (2012)) study the effect of directors’ age and tenure (as proxies for reputational concerns) on the likelihood that they take shareholder-friendly actions, these papers do not look at the interaction of directors’ reputational concerns with other firms’ corporate governance practices.

Another factor that can affect directors’ incentives to take shareholder-friendly actions is the degree of transparency about their actions. In 2004, the SEC adopted a law requiring firms to publicly disclose if one of their directors leaves the board due to a disagreement. A similar 2004 law in China requires firms to disclose if one of their independent directors votes in dissent. The analysis in Section 4.1 provides implications for the effect of these laws on directors’ behavior and shows that the effect of transparency depends on whether a shareholder-friendly reputation is rewarded in the labor market. In particular:
**Prediction 4** Greater boardroom transparency increases (decreases) directors’ incentives to take shareholder-friendly actions if corporate governance of other firms is strong (weak).

6 Conclusion

This paper develops a model of the labor market for directors and studies how directors’ reputational concerns affect corporate governance, the structure of the board, and shareholder value. Importantly, whether directors would like to build a reputation for being shareholder-friendly or management-friendly, is endogenous and depends on the allocation of control between shareholders and managers in other firms. In particular, the labor market only rewards directors for being shareholder-friendly if corporate governance in most firms is strong.

Our main result is that directors’ reputational concerns create corporate governance externalities between firms. Stronger governance in one firm leads to stronger governance in other firms and vice versa, and this spillover effect is stronger when directors’ concerns about reputation are stronger. As a result, an equilibrium with strong aggregate governance can co-exist with an equilibrium with weak aggregate governance, suggesting that countries with similar characteristics can have different governance systems. We also show that when directors’ reputation in the labor market becomes more important for them, strong governance systems become stronger but weak systems become even weaker. This implies that the effect of certain regulations, such as restricting the number of board seats an individual can hold or increasing transparency of board decision-making, crucially depends on the existing state of corporate governance. Our analysis provides new empirical predictions about director appointments and peer effects in corporate governance.

The framework developed in the paper can be extended to other settings where an agent’s choice affects both his reputation in the labor market and the type of reputation or skills that are valued at his workplace. Such settings include the choice of corporate culture by the CEO, an academic’s choice of research agenda, and the adoption of new technologies.

**Appendix**

This Appendix contains the proofs of the main results. The Supplementary Appendix contains the analysis of the extensions of the model.

**Solution concept.** A Perfect Bayesian Equilibrium is a set of directors’ effort strategies $e_i^*(\theta_i), e_j^*(\theta_j)$, beliefs about the type of directors $\pi_i^*(\chi_i)$, and firms’ hiring strategies $h_i^*(\chi_i, \pi_j)$ such that the following conditions are satisfied:
1. The effort decision of director of firm $i$ maximizes his expected utility, where the beliefs about the director’s type $\pi^*_i(\chi_i)$, the effort strategy of the other director $e^*_j(\theta_j)$, and firm $j$’s hiring strategy $h^*_j(\chi_j, \pi_i)$ are taken as given.

2. Whenever possible, beliefs about directors’ types are consistent with Bayes’ rule, where directors’ effort strategies $e^*_i(\theta_i)$, $e^*_j(\theta_j)$ are taken as given.

3. The hiring decision of the controlling party of firm $i$ maximizes its expected utility, where beliefs $\pi^*_j(\chi_j)$ and the directors’ effort strategies $e^*_i(\theta_i)$, $e^*_j(\theta_j)$ are taken as given.

**Proof of Lemma 1.** Director $i$ maximizes (4) taking $e_j(\theta)$ and $\pi^*_i(\chi_j)$ as given. From (4) it follows that $U_i(1, \theta_i) > U_i(0, \theta_i)$ if and only if

$$\Delta(\theta_i) > \alpha \lambda (1 - \lambda) \left[ \Gamma(\pi^*_i(0), \tau_j) - \Gamma(\pi^*_i(1), \tau_j) \right],$$

where

$$\Gamma(\pi^*_i(0), \tau_j) - \Gamma(\pi^*_i(1), \tau_j) = (2\tau_j - 1) \cdot [1 \{\pi^*_i(0) \geq \mathbb{E}[\theta]\} - 1 \{\pi^*_i(1) \geq \mathbb{E}[\theta]\}],$$

which is independent of $\theta_i$. Since $\lim_{\theta \to -\infty} \Delta(\theta_i) = \infty$, $\lim_{\theta \to -\infty} \Delta(\theta_i) = -\infty$, and $\frac{\partial \Delta(\theta_i)}{\partial \theta} > 0$, then for any strategy $e_j(\theta)$ and beliefs $\pi^*_i(\chi)$, there exists $\theta^*_i$ such that $U_i(1, \theta_i) > U_i(0, \theta_i)$, and hence $e_i(\theta_i) = 1$, if and only if $\theta_i > \theta^*_i$. ■

**Proof of Lemma 2.** A symmetric equilibrium exists if the equation $\beta(\theta^*) = \theta^*$ has a solution. Since $\beta(\theta^*)$ is bounded and continuous, by the intermediate value theorem, a solution (not necessarily unique) always exists. Suppose, next, that there exists some asymmetric equilibrium in which $\theta^*_i > \theta^*_j$. In equilibrium, $\theta^*_i = \beta(\theta^*_j)$ and $\theta^*_j = \beta(\theta^*_i)$. Therefore, $\beta(\theta^*_j) > \beta(\theta^*_i)$. Since $\beta$ is strictly increasing, this inequality implies $\theta^*_j > \theta^*_i$, which is a contradiction. ■

**Proof of Proposition 1.** (i) To prove that both a management-friendly and a shareholder-friendly equilibrium exist for a given $\alpha$, we need to prove that the function $\Psi(\theta, \alpha) = \beta(\theta, \alpha) - \theta$ has at least one root on $(\mu, +\infty)$ and at least one root on $(-\infty, \mu)$, where $\beta(\theta, \alpha)$ is given by (7).
Since $\beta(\theta, \alpha)$ is bounded on $(-\infty, +\infty)$, $\lim_{\theta \to -\infty} \Psi(\theta, \alpha) = +\infty$ and $\lim_{\theta \to +\infty} \Psi(\theta, \alpha) = -\infty$. Hence, by the intermediate value theorem, both types of equilibria exist if there exist $\theta_1 < \mu$ and $\theta_2 > \mu$ such that $\Psi(\theta_1, \alpha) < 0 < \Psi(\theta_2, \alpha)$. We next show that this condition is satisfied for a large enough $\alpha$. Fix any $\theta_1 < \mu$ and $\theta_2 > \mu$. By (7), $\lim_{\alpha \to -\infty} \Psi(\theta_1, \alpha) = -\infty$ and $\lim_{\alpha \to -\infty} \Psi(\theta_2, \alpha) = +\infty$. Hence, there exists $\alpha$ such that for any $\alpha \geq \alpha$, $\Psi(\theta_1, \alpha) < 0 < \Psi(\theta_2, \alpha)$. Hence, for any $\alpha \geq \alpha$ there exists at least one shareholder-friendly and at least one management-friendly equilibrium.\(^{27}\) Consider the set $\tilde{A} = \{\alpha \geq 0 : \text{for any } \alpha \geq \alpha, \text{ there exists at least one shareholder-friendly and at least one management-friendly equilibrium}\}$. The above arguments prove that this set is non-empty. Then $\tilde{\alpha}$ in the statement of the proposition is defined as $\inf \{A \}$.

(ii) First, we prove that for any $\alpha_0 < \tilde{\alpha}$, all equilibria must be of the same type. Suppose, on the contrary, that both types of equilibria exist for some $\alpha_0 < \tilde{\alpha}$, i.e., there exist $\theta_1 < \mu$ and $\theta_2 > \mu$ such that $\Psi(\theta_1, \alpha_0) = 0$. We next show that in this case, both types of equilibria exist for any $\alpha > \alpha_0$ as well, which contradicts the definition of $\tilde{\alpha}$ as $\inf \{A \}$. Indeed, for any $\alpha > \alpha_0$, $\Psi(\theta_1, \alpha) < \Psi(\theta_1, \alpha_0) = 0$ and $\Psi(\theta_2, \alpha) > \Psi(\theta_2, \alpha_0) = 0$. Since $\lim_{\theta \to -\infty} \Psi(\theta, \alpha) = +\infty$ and $\lim_{\theta \to +\infty} \Psi(\theta, \alpha) = -\infty$, then by the intermediate value theorem, there exist $\theta_1' \in (-\infty, \theta_1)$ and $\theta_2' \in (\theta_2, +\infty)$ such that $\Psi(\theta_1', \alpha) = 0$. These are the shareholder-friendly and management-friendly equilibria for $\alpha > \alpha_0$.

Next, suppose $\Delta^{-1}(0) - \mu > (>) 0$. Consider any $\alpha_0 < \tilde{\alpha}$. Since $\Psi(\mu, \alpha_0) = \Delta^{-1}(0) - \mu > (>) 0$ and since $\lim_{\theta \to +\infty} \Psi(\theta, \alpha_0) = -\infty$ (\lim_{\theta \to -\infty} \Psi(\theta, \alpha_0) = +\infty), there exists $\tilde{\theta} > (>) \mu$ such that $\Psi(\tilde{\theta}, \alpha_0) = 0$, i.e., there exists at least one management-friendly (shareholder-friendly) equilibrium. Since, as shown above, all equilibria are of the same type, then all equilibria must be management-friendly (shareholder-friendly).

(iii) Note that $\frac{\partial \beta(\theta, \alpha)}{\partial \theta} = 2\alpha \lambda (1 - \lambda) f(\theta) \cdot d(\alpha \lambda (1 - \lambda) (2F(\theta) - 1))$, where $d(\cdot) = (\Delta^{-1})'$. Since $F(\theta) \in [0, 1]$ and $d(\cdot)$ is continuous, there exists $\tilde{d}$ such that $|d(\alpha \lambda (1 - \lambda) (2F(\theta) - 1))| < \Delta(\mu)$.

\(^{27}\) The same arguments imply that if $\Delta(\mu) \neq 0$, then for almost all $\alpha \geq \tilde{\alpha}$, there exists at least one stable shareholder-friendly and at least one stable management-friendly equilibrium. Indeed, since $\Psi(\theta_2, \alpha) > 0$ and $\lim_{\theta \to +\infty} \Psi(\theta, \alpha) = -\infty$, there exists at least one point on $(\theta_2, +\infty)$ where $\Psi(\theta, \alpha) = 0$ and $\Psi(\theta, \alpha)$ crosses the x-axis from above, i.e., at least one stable management-friendly equilibrium. The same argument holds for a stable shareholder-friendly equilibrium. The condition $\Delta(\mu) \neq 0$ allows to rule out situations when $\Psi(\theta, \alpha)$ is tangent to the x-axis, as in the proof of Proposition 2.
\( \tilde{d} \) for all \( \theta \) and all \( \alpha < 1 \). Since, by assumption, \( f(\cdot) \) is bounded, there exists \( \tilde{f} \) such that \( f(\theta) < \tilde{f} \) for all \( \theta \in \mathbb{R} \). Then, \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta} < 2\alpha \lambda (1 - \lambda) \tilde{f} \tilde{d} \) and hence there exists \( \alpha > 0 \) such that for any \( \alpha < \alpha \), \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta} < 0.5 \).

We next prove that for any \( \alpha < \alpha \), the equilibrium is unique. Suppose this is not true, and \( \theta_1 < \theta_2 \) are two equilibria for some \( \alpha < \alpha \). Then \( \Psi(\theta_1, \alpha) = \Psi(\theta_2, \alpha) = 0 \), and since \( \Psi(\theta, \alpha) \) is continuous and differentiable, by the mean value theorem, there exists \( \tilde{\theta} \in (\theta_1, \theta_2) \) such that \( \frac{\partial \Psi(\tilde{\theta}, \alpha)}{\partial \theta} = 0 \iff \frac{\partial \beta(\theta, \alpha)}{\partial \theta} = 1 \). This contradicts the fact that \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta} < 0.5 \) for all \( \theta \). \( \blacksquare \)

**Proof of Proposition 2.** First, note that the assumption \( \Delta(\mu) \neq 0 \) ensures that \( \theta^* = \mu \) can never be an equilibrium. Indeed, it it were an equilibrium, (7) would imply \( \mu = \beta(\mu) = \Delta^{-1}(0) \), which would contradict \( \Delta(\mu) \neq 0 \).

We start by proving the supplementary result that if \( \Delta(\mu) \neq 0 \), then for all \( \alpha \in \mathbb{R} \) except for a set of Lebesgue measure zero, \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta}|_{\theta = \theta^*} \neq 1 \) in any equilibrium \( \theta^* \). To prove this, consider the function \( \Psi(\theta, \alpha) = \beta(\theta, \alpha) - \theta \). In any equilibrium \( \theta^* \), \( \Psi(\theta^*, \alpha) = 0 \). By (7),

\[
\frac{\partial \Psi(\theta, \alpha)}{\partial \alpha}|_{\theta^*} = \lambda (1 - \lambda) (2F(\theta^*) - 1) \times d(\alpha \lambda (1 - \lambda) (2F(\theta^*) - 1))
\]

where \( d(\cdot) = (\Delta^{-1})' \). By assumption, \( \Delta'(\theta) > 0 \) and hence \( (\Delta^{-1})' > 0 \). Moreover, since \( \theta^* \neq \mu \), as shown above, then \( 2F(\theta^*) - 1 \neq 0 \). Thus, in any equilibrium, \( \frac{\partial \Psi(\theta, \alpha)}{\partial \alpha}|_{\theta^*} \neq 0 \) and hence the Jacobian \( d\Psi(\theta, \alpha) = \left( \frac{\partial \Psi(\theta, \alpha)}{\partial \theta}, \frac{\partial \Psi(\theta, \alpha)}{\partial \alpha} \right) \) has rank 1. By the Transversality Theorem (e.g., Proposition 17.D.3 in Mas-Colell, Whinston and Green (1995)), \( \frac{\partial \Psi(\theta, \alpha)}{\partial \theta}|_{\theta = \theta^*} \neq 0 \iff \frac{\partial \beta(\theta, \alpha)}{\partial \theta}|_{\theta = \theta^*} \neq 1 \) in any equilibrium \( \theta^* \) for all \( \alpha \in \mathbb{R} \) except for a set of Lebesgue measure zero.

Next, consider any \( \alpha \) for which \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta}|_{\theta = \theta^*} \neq 1 \) in all equilibria. Since \( \beta(\cdot) \) is bounded and increasing, by Tarski’s Fixed Point Theorem, \( \beta(\cdot) \) has the least and the greatest fixed points (equilibria). Denote the greatest equilibrium by \( \tilde{\theta}^* \) and note that it must be stable. Indeed, since \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta}|_{\theta = \tilde{\theta}^*} \neq 1 \), then \( \tilde{\theta}^* \) is unstable only if \( \frac{\partial \beta(\theta, \alpha)}{\partial \theta}|_{\theta = \tilde{\theta}^*} > 1 \). In this case, there exists \( \hat{\theta} > \tilde{\theta}^* \) such that \( \beta(\hat{\theta}, \alpha) = \tilde{\theta}^* > 0 \). Since \( \beta(\cdot) \) is bounded, then \( \lim_{\theta \to -\infty} \beta(\theta, \alpha) = -\infty \).

Since the function \( \beta(\theta, \alpha) - \theta \) is continuous, the intermediate value theorem implies that there exists \( \theta^* > \hat{\theta} \) such that \( \beta(\theta^*, \alpha) = \theta^* = 0 \). Since \( \theta^* > \tilde{\theta}^* \), this contradicts the fact that \( \tilde{\theta}^* \) is
Proof of Proposition 3. Consider any parameter \( p \) and any equilibrium \( \theta^* \). Using the implicit function theorem for the equality \( \beta (\theta^*) - \theta^* = 0 \), we get \( \frac{\partial \theta^*}{\partial p} = \frac{\frac{\partial \beta(\theta)}{\partial \theta}}{1 - \frac{\partial \beta(\theta)}{\partial \theta} |_{\theta=\theta^*}} \). Since \( \frac{\partial \beta(\theta)}{\partial \theta} |_{\theta=\theta^*} < 1 \) in a stable equilibrium, then for any stable equilibrium \( \theta^* \),

\[
\text{sgn} \left( \frac{\partial \theta^*}{\partial p} \right) = \text{sgn} \left( \frac{\partial \beta(\theta)}{\partial \theta} \bigg|_{\theta=\theta^*} \right). \tag{A1}
\]

Note that the opposite equality is satisfied for any non-stable equilibrium.

From (7) and the fact that \( \Delta^{-1}(\cdot) \) is a strictly increasing function, it follows that \( \frac{\partial \beta(\theta)}{\partial \sigma} > 0 \) \( \Leftrightarrow \tau^* > 0.5 \). In addition, when \( c(\theta) = c + c_0(\theta) \), \( \Delta^{-1}(\cdot) \) is a strictly increasing function of \( c \), and hence \( \frac{\partial \beta(\theta)}{\partial c} > 0 \). The comparative statics of \( \tau^* \) with respect to \( c \) and \( \alpha \) then follows from (A1), the fact that \( \tau^* = 1 - F(\theta^*) \), and that \( F(\cdot) \) does not depend on \( c \) and \( \alpha \).

By definition of FOSD, \( \frac{\partial F(\kappa, \theta)}{\partial \kappa} < 0 \) for any \( \theta \) and hence \( \frac{\partial \beta(\theta)}{\partial \kappa} < 0 \), which implies that \( \theta^* \) decreases with \( \kappa \). Since \( F(\kappa, \theta) \) decreases with \( \kappa \) for a given \( \theta \), then \( \tau^* = 1 - F(\kappa, \theta^*) \) increases with \( \kappa \). The implicit assumption in this analysis is that the distribution of outside candidates changes with \( \kappa \) as well, so that the expectations of the two distributions remain equal.

Finally, according to the definition of Diamond and Stiglitz (1974), the difference between two distributions is a simple mean-preserving spread if (a) the means of the distributions are the same, and (b) there exists a single crossing point \( \hat{\theta} \) such that \( F(\sigma_2, \theta) \geq F(\sigma_1, \theta) \) if and only if \( \theta \leq \hat{\theta} \). If the distributions are symmetric, their medians equal their means and hence \( F(\sigma_2, \mu) = F(\sigma_1, \mu) = 0.5 \), where \( \mu \) is the mean of both distributions. Thus, \( \mu \) is the single crossing point of the distributions. It follows that \( \frac{\partial \beta(\theta)}{\partial \sigma} > 0 \Leftrightarrow \frac{\partial F(\sigma, \theta)}{\partial \sigma} > 0 \Leftrightarrow \theta < \mu \Leftrightarrow \tau^* > 0.5 \). Hence, \( \theta^* \) increases with \( \sigma \) if and only if \( \tau^* > 0.5 \). Since the effect of \( \sigma \) on \( F(\sigma, \theta) \) for a fixed \( \theta \) is in the same direction, then \( \tau^* = 1 - F(\sigma, \theta^*) \) increases with \( \sigma \) if and only if \( \tau^* < 0.5 \).
Supplementary Appendix for Online Publication

The Supplementary Appendix contains all the assumptions, formal results, and proofs of the extensions discussed in Section 4 of the paper. It also contains an extension of the model that allows for contingent reward from additional board seats.

1 Transparency

Suppose that if the director does not exert effort, the manager maintains control for sure, and if the director exerts effort, shareholders get control with probability $\rho \in (0, 1]$. The basic model corresponds to $\rho = 1$. The allocation of control $(x_i, x_j)$ is publicly observable. Before the labor market stage, a public signal $s_i$ of each director’s effort decision is revealed. The signals are independent across firms and take the following form. With probability $\eta$ the signal perfectly reveals the director’s effort decision, that is, $s_i = e_i$. With probably $1 - \eta$ the signal is pure noise and does not reveal any information about $e_i$. That is, $s_i = \phi$, where $\phi$ is pure noise. Whether the signal of firm $i$ is informative or pure noise is publicly known. Thus, higher $\eta$ corresponds to greater transparency about directors’ actions. At the time of making the effort decisions, directors do not know whether their effort will be revealed or not.

In the proof of Proposition B.1 below, we show that the best response function for this modified setup is given by

$$\beta(\theta) = \Lambda_\rho^{-1} \left( \alpha \lambda (1 - \lambda) (\rho + \eta (1 - \rho)) \left( 2F(\theta) - 1 + \frac{1 - \rho}{\rho} \right) \right),$$

(B1)

where $\Lambda_\rho \equiv \Delta(\theta_i) - \frac{1 - \rho}{\rho} c(\theta_i)$. Note that for any $\rho < 1$, $\beta(\theta)$ is increasing in $\eta$ if and only if $\rho (1 - F(\theta)) < 0.5$. Since the probability of shareholder control is $\tau^* = \rho (1 - F(\theta^*))$, this implies, similar to the proof of Proposition 3, that in any stable equilibrium, greater transparency (higher $\eta$) increases the probability of shareholder control $\tau^*$ if and only if the equilibrium is shareholder-friendly ($\tau^* > 0.5$).

We conclude with the following result.

---

28 We make an additional assumption that $c(\theta)$ is weakly decreasing with $\theta$. This guarantees that $\Lambda_\rho$ is monotonic.

29 The comparative statics of $\theta^*$ with respect to $\rho$ implies that $\frac{\partial \theta^*}{\partial \rho} < 0$ when $c(\theta) \geq 0$ for all $\theta$. Intuitively, the higher is $\rho$, the more effective is the directors’ effort and hence the higher is the net benefit from exerting effort. To show this, it is easy to see that $\frac{\partial \beta(\theta)}{\partial \rho} \big|_{\theta = \theta^*}$ is negative when $c(\theta) \geq 0$ for all $\theta$.
Proposition B.1 In any stable equilibrium, higher transparency increases the probability of shareholder control if and only if the equilibrium is shareholder-friendly.

Proof. Let \( \pi(\chi_i, s_i) \) be the equilibrium reputation of director \( i \) conditional on all public information. Note that \( \pi^*_i (1, 1) = \pi^*_i (0, 1) \). Since shareholder control is obtained only if the director exerts effort, \( \pi^*_i (1, s_i) = \pi^*_i (1, 1) \) for any \( s_i \). Then, the expected utility \( U_i (e_i, \theta_i) \) of director \( i \), given his type \( \theta_i \) and effort \( e_i \), and taking as given beliefs \( \pi^*_i (\cdot, \cdot) \) and the probability of shareholder control in the other firm \( \tau_j \), can be written as

\[
U_i (0, \theta_i) = v (0, \theta_i) + \alpha \lambda (1 - \lambda) \left[ \eta \Gamma (\pi^*_i (0, 0), \tau_j) + (1 - \eta) \Gamma (\pi^*_i (0, \phi), \tau_j) \right] + \lambda u_{\text{resign}}
\]

and

\[
U_i (1, \theta_i) = \left[ \rho v (1, \theta_i) + (1 - \rho) v (0, \theta_i) \right] + \alpha \lambda (1 - \lambda) \left[ (\rho + \eta (1 - \rho)) \Gamma (\pi^*_i (1, 1), \tau_j) + (1 - \eta) (1 - \rho) \Gamma (\pi^*_i (0, \phi), \tau_j) \right] - c (\theta_i) + \lambda u_{\text{resign}}.
\]

It follows that \( U_i (1, \theta_i) > U_i (0, \theta_i) \) if and only if

\[
\rho \Delta (\theta_i) - (1 - \rho) c (\theta_i) > \alpha \lambda (1 - \lambda) \left[ \eta \Gamma (\pi^*_i (0, 0), \tau_j) + \rho (1 - \eta) \Gamma (\pi^*_i (0, \phi), \tau_j) - (\rho + \eta (1 - \rho)) \Gamma (\pi^*_i (1, 1), \tau_j) \right]. \tag{B2}
\]

Since the right-hand side does not depend on \( \theta_i \), and since \( c (\theta_i) \) is decreasing, Lemma 1 continues to hold and hence \( \pi^*_i (1, 1) = \mathbb{E} [\theta | \theta > \theta^*_i] \), \( \pi^*_i (0, 0) = \mathbb{E} [\theta | \theta \leq \theta^*_i] \), and

\[
\pi^*_i (0, \phi) = \frac{\Pr [\theta \leq \theta^*_i] \mathbb{E} [\theta | \theta \leq \theta^*_i] + \Pr [\theta > \theta^*_i] (1 - \rho) \mathbb{E} [\theta | \theta > \theta^*_i]}{\Pr [\theta \leq \theta^*_i] + \Pr [\theta > \theta^*_i] (1 - \rho)}.
\]

The function \( \pi^*_i (0, \phi) \) is decreasing in \( \rho \) and takes values in the interval \((\mathbb{E} [\theta | \theta \leq \theta^*_i], \mathbb{E} [\theta])\) for \( \rho \in (0, 1) \). It is immediate to see that Lemma 2 continues to hold. According to (3), the reputation term in inequality (B2) equals \([\rho + \eta (1 - \rho)] (1 - 2\tau^*)\). This implies that the best response function is given by (B1).
2 Shareholder activism

We extend the model and assume that in each firm there is an activist investor who can incur a cost $g_i$ to intervene and transfer control to shareholders before directors make their effort decisions. If the activist intervenes, shareholders get control regardless of directors’ actions at the next stage.\footnote{The assumption that upon intervention shareholders get control for sure, regardless of directors’ actions, is made for simplicity. The results would be similar if shareholder intervention led to a positive probability of shareholder control in cases when directors do not transfer control to shareholders.} The activists’ intervention decisions are publicly observable and made simultaneously. The cost $g_i$ is distributed according to a distribution function $G(\cdot)$ on $[0, +\infty)$ and is privately observed by the activist. Suppose that the activist’s utility from shareholder control is $u(\chi_i)$. Without loss of generality, we can set $u(0) = 0$ and $u(1) = v > 0$.

Let $\omega_i$ be the probability of shareholder intervention in firm $i$. Consider firm $i$ and the activist’s decision whether to intervene taking as given the intervention strategy of the activist in firm $j$. If the activist intervenes, then $\chi_i = 1$ and the activist’s utility is $u - g_i$. If the activist does not intervene, her utility depends on the director’s decision whether to exert effort, which, in turn, depends on whether the activist in firm $j$ transferred control to shareholders. Consider two cases. First, if the activist in firm $j$ does not intervene, the subgame is equivalent to the game in the basic model and hence $\Pr(e_i = 1) = \Pr(\theta_i > \theta_j^*) = \tau^*$, the equilibrium probability that directors exert effort in the basic model. Second, if the activist in firm $j$ intervenes, then $\chi_j = 1$ regardless of directors’ decisions at the next stage. In this case, director $i$ understands that he will be invited to the board of firm $j$ if and only if he transfers control to shareholders. Hence, the director exerts effort if and only if

$$v(1, \theta_i) - c(\theta_i) + \alpha\lambda(1 - \lambda) > v(0, \theta_i) \Leftrightarrow \theta_i > \Delta^{-1}(-\alpha\lambda(1 - \lambda))$$

Denote

$$\hat{\tau} = 1 - F\left(\Delta^{-1}(-\alpha\lambda(1 - \lambda))\right)$$

the probability of shareholder control in firm $i$ in this subgame. It follows that the activist in firm $i$ intervenes if and only if

$$u - g_i > (1 - \omega_j)\tau^*v + \omega_j\hat{\tau} \Leftrightarrow g_i < v\left[1 - (1 - \omega_j)\tau^* - \omega_j\hat{\tau}\right]$$

Hence, the activist follows a threshold strategy and intervenes only if her costs do not exceed a certain threshold. Consider the best response function $\gamma_i(g_j)$ of activist $i$, taking as given that
activist $j$ intervenes if and only if her cost is below $g_j$. Then $\gamma_i (g_j) = \gamma (g)$, where

$$\gamma (g) = v [1 - (1 - G (g)) \tau^* - G (g) \tilde{\tau}]$$.

(B3)

Note that the function $\gamma (g)$ is decreasing: $\frac{\partial \gamma}{\partial g} = vG' (g) (\tau^* - \tilde{\tau}) < 0$. Indeed, $\tilde{\tau} > \tau^*$ because a director’s incentives to establish a shareholder-friendly reputation are higher when he knows for sure that the other firm is controlled by shareholders, compared to the case when there is uncertainty. Also, $\gamma (0) = v [1 - \tau^*]$, $\lim_{g \to \infty} \gamma (g) = v [1 - \tilde{\tau}]$ and hence, for a given $\tau^*$, there exists a unique equilibrium at the shareholder activism stage. This equilibrium is symmetric and characterized by some threshold $g^*$ and probability of shareholder activism $\omega^* = G (g^*)$.

Consider the comparative statics of the extended model. If $g^*$ is the equilibrium intervention threshold, then shareholder welfare net of intervention costs (i.e., the activist’s welfare) equals

$$W (g^*) = v \Pr (\chi_i = 1) - \int_0^{g^*} xdG (x)$$,

where $\Pr (\chi_i = 1) = \omega^* + (1 - \omega^*) [\tau^* (1 - \omega^*) + \tilde{\tau} \omega^*]$ and $\omega^* = G (g^*)$. Using (B3) and the fact that $\gamma (g^*) = g^*$, we can rewrite $\Pr (\chi_i = 1)$ as $1 - \frac{g^*}{v} + G (g^*) \frac{\omega^*}{v}$. Hence,

$$W' (g^*) = \frac{\partial \Pr (\chi_i = 1)}{\partial g^*} v - g^* G' (g^*) = G (g^*) - 1 < 0$$.

Thus, the activist’s welfare is lower when there is more intervention in equilibrium ($g^*$ is higher). The comparative statics of $g^*$ with respect to $c, \kappa$ and $\alpha$ coincides with the comparative statics of $\gamma (g)$. Since $\tau^*$ and $\tilde{\tau}$ decrease with $c$ and increase with $\kappa$, then $g^*$ increases with $c$ and decreases with $\kappa$. Intuitively, shareholder activism is a substitute for the board of directors: when the board is ineffective (director’s costs of effort are high or the likelihood of shareholder-friendly directors is low), there is more shareholder activism. The effect of $\alpha$ on $g^*$ depends on whether the equilibrium is shareholder-friendly or management-friendly. If the equilibrium is shareholder-friendly, then both $\tau^*$ and $\tilde{\tau}$ increase with $\alpha$ and hence $g^*$ decreases with $\alpha$. However, in a management-friendly equilibrium, $\tau^*$ decreases with $\alpha$, while $\tilde{\tau}$ increases with $\alpha$, and hence the effect of $\alpha$ on $g^*$ depends on the equilibrium level of $g^*$.

Taken together, these arguments imply that shareholder welfare net of intervention costs decreases with $c$, increases with $\kappa$, and can either increase or decrease with $\alpha$ depending on whether the equilibrium is shareholder-friendly or management-friendly.
3 Board size

Suppose that the board of each firm consists of $K \geq 2$ directors. Directors’ types are independent across and within firms and are drawn from the same distribution $F$. At the first stage, all directors simultaneously decide whether to exert effort. If at least $T \in \{1, ..., K\}$ directors exert effort, then shareholders obtain control, and otherwise, the management retains control. Individual effort decisions are not observable and hence do not directly impact directors’ reputation in the labor market, but the allocation of control in each firm is observable.

At the second stage, for each firm, there is a probability $\delta \equiv \lambda K \in (0, 1)$ that one of its directors will be hit by a resignation shock, will no longer participate in the labor market, and the firm will have to search for a new director. Each of $K$ directors has an equal chance of being hit by the shock. Thus, for each director, the unconditional probability of having to resign is $\lambda$. We also assume that if several directors have the same reputation, they are equally likely to be invited to the board of the other firm. This setup coincides with the basic model when $K = 1$. Then, conditional on $\chi_i = \chi_j$, the probability that a director of firm $i$ is invited to the board of firm $j$ is $\delta \left( (1 - \delta) \frac{1}{K} + \frac{K-1}{K} \right)^{K-1} = \lambda$ for any $K \geq 2$. Thus, the expected value of reputation $\pi$ is equal to $\alpha \lambda \Gamma (\pi, \tau)$ for any $K \geq 2$.

Consider any director’s decision whether to exert effort to transfer control to shareholders. Let $p^*$ be the equilibrium probability that exactly $T - 1$ of other $K - 1$ directors exert effort. In this event, the director’s decision is pivotal for the outcome, that is, shareholders get control if and only if the director exerts effort. In all other cases, the director’s decision has no impact on the outcome. Since the cost of effort is incurred whether or not the director is pivotal, the cost of effort effectively increases to $\frac{c^*(\theta)}{p^*}$. Following similar arguments to those in Lemma 1, it can be shown that in any equilibrium directors follow threshold strategies. Under symmetric threshold strategies $\theta^*$, the probability of being pivotal is $p^* = p(\theta^*) \equiv C_{T-1}^{K-1} (1 - F(\theta^*))^{T-1} F(\theta^*)^{K-T}$.

Note that board size affects directors’ incentives through two channels. The first channel is due to externalities between firms and is discussed in detail below. The second channel is due to the free-riding problem within the board, which is reflected in the higher effective cost of effort $\frac{c^*(\theta)}{p(\theta^*)}$: a director’s incentives to exert effort depend on both the size of his board and the voting rule his board uses. Since the focus of our paper is on externalities between firms, we shut down the free-riding channel in subsequent analysis by assuming that $c(\theta) = 0$.

Consider symmetric threshold strategies. Then $\theta^*$ is an equilibrium if and only if it satisfies $\theta^* = \beta_{K,T}(\theta^*)$, where $\beta_{K,T}(\theta) = \Delta^{-1} (\alpha \lambda (1 - 2 \tau(\theta)))$
is the best response function of each director and

$$\tau(\theta) = \sum_{t=T}^{K} C^t (1 - F(\theta))^t F(\theta)^{K-t}$$

is the likelihood that control is obtained by shareholders of the other firm. As in the basic model, we call an equilibrium $\theta^*$ shareholder-friendly if $\tau(\theta^*) > 0.5$.

The expression for $\beta_{K,T}(\theta)$ shows that even though $c(\theta) = 0$, the number of directors at the other firm affects the best response function of each director due to externalities between firms. This is captured by the dependence of $\tau(\theta)$ on $K$. Since $\tau(\theta)$ decreases with $\theta$ (see the proof of Proposition B.2), the best response function is increasing in $\theta$. Hence, the extended model exhibits strategic complementarity as well. The next result analyzes the effect of board size $K$ and voting requirement $T$ on directors’ incentives to exert effort and on the equilibrium probability of shareholder control $\tau^* \equiv \tau(\theta^*)$ in stable equilibria.\textsuperscript{31}

**Proposition B.2** Suppose $c(\theta) = 0$ and consider any stable equilibrium. Then:

(i) If $T$ is fixed, then $\tau^*$ increases with $K$.

(ii) If $T = K$ (unanimity rule), then $\tau^*$ decreases with $K$.

(iii) If $K$ is odd and $T = \frac{K+1}{2}$ (majority rule), then $\tau^*$ increases with $K$ if and only if the equilibrium is shareholder-friendly.

(iv) If $K$ is fixed, then $\tau^*$ decreases with $T$.

**Proof.** First, note that $\tau(\theta)$ decreases with $\theta$. Indeed, let $B_{K,p}(x)$ be the cumulative density function of a Binomial distribution with parameters $(K,p)$. Then, by the properties of the Binomial distribution, $B_{K,p}(x)$ is first-order stochastically increasing as $p$ increases, i.e., $B_{K,p_2}(x) < B_{K,p_1}(x)$ for $p_2 > p_1$. Note that $\tau(\theta) = 1 - B_{K,1-F(\theta)}(T-1)$. Since $F(\theta)$ increases with $\theta$, $\tau(\theta)$ decreases with $\theta$.

Since $\theta^*$ is a stable equilibrium, then, similar to the basic model, the comparative statics of $\theta^*$ with respect to $K$ or $T$ coincides with the comparative statics of $\beta_{K,T}(\theta)$ with respect to this parameter. In addition, since $\tau(\theta)$ decreases with $\theta$ and the comparative statics of $\theta^*$

\textsuperscript{31}The comparative statics results hold for any stable equilibrium that continues to exist with a change in $K$ and $T$. However, since a change in $K$ and $T$ changes the best response function in a discrete way, a given equilibrium might disappear.
with respect to $K$ or $T$ is the opposite of the comparative statics of $\tau (\theta )$ with respect to this parameter, then the comparative statics of $\tau^* = \tau (\theta^*)$ with respect to $K$ or $T$ is the opposite of the comparative statics of $\beta_{K,T} (\theta )$ with respect to this parameter.

Consider part (iv) and part (i). Recall $\tau (\theta ) = 1 - B_{K,1-F(\theta)} (T - 1)$. By the properties of the Binomial distribution, $\tau (\theta )$ decreases with $T$ and hence $\beta_{K,T} (\theta )$ increases with $T$. Moreover, $B_{K_2,p} (x) < B_{K_1,p} (x)$ for $K_2 > K_1$. Hence, $\tau (\theta )$ increases with $K$ and $\beta_{K,T} (\theta ) (\theta )$ decreases with $K$ for a fixed $T$.

Consider part (ii). When $T = K$ then $\tau (\theta ) = (1 - F (\theta)) K$, which decreases with $K$ for any $\theta$. Hence, $\beta_{K,T} (\theta ) (\theta )$ increases with $K$.

Consider part (iii). We show that $\beta_{K,T} (\theta )$ increases with $K$ if and only if $\tau (\theta ) < 0.5$.

Consider the function

$$ g(p, K) = \sum_{t = K+1}^{K} C_t^K p^t (1 - p)^{K-t} $$

Note that

$$ 1 - g(p, K) = \sum_{t=0}^{K+1} C_t^K p^t (1 - p)^{K-t} = \sum_{s=K}^{K+1} C_{K-s}^K p^{K-s} (1 - p)^s = \sum_{t=K+1}^{K} C_t^K p^{K-t} (1 - p)^t $$

and hence

$$ g(p, K) > 0.5 \iff \sum_{t=K+1}^{K} C_t^K \left[ p^t (1 - p)^{K-t} - p^{K-t} (1 - p)^t \right] > 0 $$

Note that for any $t > K/2$,

$$ p^t (1 - p)^{K-t} > p^{K-t} (1 - p)^t \iff \left( \frac{p}{1-p} \right)^{2t-K} > 1 \iff p > 0.5 $$

and hence $g(p, K) > 0.5 \iff p > 0.5$. Since the function $g(p, K)$ increases with $K$ if and only if $p > 0.5$, it follows that $g(p, K)$ increases with $K$ if and only if $g(p, K) > 0.5$. Since $\tau (\theta ) = g(1 - F (\theta), K)$, then $\tau (\theta )$ increases with $K$ if and only if $\tau (\theta ) > 0.5$ and hence $\beta_{K,T} (\theta )$ increases with $K$ if and only if $\tau (\theta ) < 0.5$.

4 Multiple firms

Consider the extension of the model to $N \geq 2$ firms described in Section 4.4. We search for symmetric equilibria, which are characterized by a threshold $\theta$ and $\tau = 1 - F (\theta)$, the probability
that shareholders obtain control. Consider a director who was not hit by a resignation shock. Let \( k \) be the number of shareholder-controlled firms out of the other \( N - 1 \) firms. Among these firms, let \( d_{SH} \) be the number of firms that were hit by a resignation shock and thus have demand for a new (shareholder-friendly) director. Similarly, let \( d_M \) be the number of firms with demand for a management-friendly director out of the other \( N - k \) management-controlled firms. Given \( k, d_{SH}, \) and \( d_M \), the expected number of directorships that a director with reputation \( \pi \) will obtain is:

\[
E[d] = \frac{d_{SH}}{k+1-d_{SH}} \text{ if } \pi \geq \mathbb{E}[\theta] \text{ and } \frac{d_M}{N-k-d_M} \text{ if } \pi < \mathbb{E}[\theta].
\]

Taking the expectation over possible realizations of \( k, d_{SH}, \) and \( d_M \), we derive the expected value of reputation.

**Lemma B.1** Given \( \tau \), the expected value of reputation is

\[
\alpha \lambda \left[ 1 - ((1 - \tau) + \lambda \tau)^{N-1} \right] \quad \text{if } \pi \geq \mathbb{E}[\theta] \quad \text{and} \quad \alpha \lambda \left[ 1 - ((1 - \tau) \lambda + \tau)^{N-1} \right] \quad \text{otherwise.}
\]

**Proof.** Explicitly, the expected value of reputation is given by

\[
\Upsilon(\pi) \equiv \alpha (1 - \lambda) \sum_{k=0}^{N-1} \left[ C_k \tau^k (1 - \tau)^{N-1-k} \sum_{i=0}^{k} \sum_{j=0}^{N-1-k} \lambda^i (1 - \lambda)^{k-i} \times \lambda^j (1 - \lambda)^{N-1-k-j} \times \Lambda(k, i, j, \pi) \right]
\]

where

\[
\Lambda(k, i, j, \pi) = \begin{cases} 
\frac{i}{k+1-i} & \text{if } \pi \geq \mathbb{E}[\theta] \\
\frac{j}{N-k-j} & \text{if } \pi < \mathbb{E}[\theta]
\end{cases}
\]

We start with the auxiliary result that

\[
\sum_{j=0}^{Y} C_j \lambda^j (1 - \lambda)^{Y-j} \times \frac{j}{Y+1-j} = \frac{\lambda}{1-\lambda} \left[ 1 - \lambda^Y \right]
\]

To see why this is the case, note that since \( C_j \frac{j}{Y+1-j} = C_{j-1} \) and since at \( j = 0 \) the expression in the summation that is in the left hand side is zero, then

\[
\sum_{j=0}^{Y} C_j \lambda^j (1 - \lambda)^{Y-j} \times \frac{j}{Y+1-j} = \sum_{j=1}^{Y} C_{j-1} \lambda^j (1 - \lambda)^{Y-j}
\]
Let $h = j - 1$, then

$$
\sum_{j=1}^{Y} C_{j-1}^{Y} \lambda^{j} (1 - \lambda)^{Y-j} = \sum_{h=0}^{Y-1} C_{h}^{Y} \lambda^{h+1} (1 - \lambda)^{Y-h-1}
$$

$$
= \frac{\lambda}{1-\lambda} \left[ \sum_{h=0}^{Y} C_{h}^{Y} \lambda^{h} (1 - \lambda)^{Y-h} - \lambda^{Y} \right]
$$

Using $\sum_{h=0}^{Y} C_{h}^{Y} \lambda^{h} (1 - \lambda)^{Y-h} = 1$ concludes this result.

Next, if $\pi < \mathbb{E} [\theta]$ then

$$
\Upsilon (\pi) = \alpha (1 - \lambda) \sum_{k=0}^{N-1} \left[ C_{k}^{N-1} \tau^{k} (1 - \tau)^{N-1-k} \times \frac{\lambda}{1-\lambda} \left[ 1 - \lambda^{N-1-k} \right] \right]
$$

$$
= \alpha \lambda \left( 1 - ((1 - \tau) \lambda + \tau)^{N-1} \right)
$$

where for the first equality we used the fact that $\sum_{i=0}^{k} C_{i}^{k} \lambda^{i} (1 - \lambda)^{k-i} = 1$ and the auxiliary result proved above, and for the second equality we used the identity $\sum_{k=0}^{n} C_{k}^{n} \times x^{k} = (1 + x)^{n}$.

Similarly, if $\pi \geq \mathbb{E} [\theta]$ then

$$
\Upsilon (\pi) = \alpha (1 - \lambda) \sum_{k=0}^{N-1} \left[ C_{k}^{N-1} \tau^{k} (1 - \tau)^{N-1-k} \times \frac{\lambda}{1-\lambda} \left[ 1 - \lambda^{k} \right] \right]
$$

$$
= \alpha \lambda \left( 1 - ((1 - \tau) + \lambda \tau)^{N-1} \right),
$$

which completes the proof. $\blacksquare$

It follows from Lemma B.1 that, similar to the basic model, a reputation for being shareholder-friendly generates a higher payoff than a reputation for being management-friendly if and only if $\tau > 0.5$. Therefore, Definition 1 of shareholder-friendly and management-friendly equilibria can be extended to any number of firms.

By Lemma B.1, an equilibrium with threshold $\theta^{*}$ exists if and only if $\theta^{*} = \beta_{N} (\theta^{*})$, where

$$
\beta_{N} (\theta) = \Delta^{-1} \left( \alpha \lambda \left[ (\lambda + (1 - \lambda) F (\theta))^N - (1 - (1 - \lambda) F (\theta))^N \right] \right).
$$

The best response function $\beta_{N} (\theta)$ coincides with (7) for $N = 2$ and is strictly increasing in $\theta$ for any $N \geq 2$. Hence, the extended model exhibits strategic complementarity as well. Moreover, using the arguments in the proof of Proposition 3, it is immediate to see that the comparative statics of $\theta^{*}$ (and hence of $\tau^{*}$) with respect to $\alpha, \kappa, c$ and $\sigma$ is the same as in the basic model.
5 Value of shareholder control

Suppose there is a random variable $\delta_i \in \{SH, M\}$ such that shareholders of firm $i$ are better off having control if $\delta_i = SH$ and are better off delegating control to the manager if $\delta_i = M$. We assume that $\delta_i$ are independent across firms, and that $\delta_i$ is director $i$’s private information. The prior probability that $\delta_i = SH$ is equal to $\psi \in (0, 1]$. Directors’ relative value from shareholder control, $v_{\delta_i}(1, \theta) - v_{\delta_i}(0, \theta)$, depends on $\delta_i$. Hence, the relative benefit from transferring control to the shareholders for a director of type $\delta_i$, $v_{\delta_i}(1, \theta) - c(\theta)$, also depends on $\delta_i$. Specifically, we assume that $\Delta_{SH}(\theta) \equiv v_{\delta_i}(1, \theta) - v_{\delta_i}(0, \theta) - c(\theta)$, also depends on $\delta_i$. We also assume that if $\delta_i = M$, then regardless of the allocation of control, the firm demands management-friendly directors.$^{32}$

Similar to the basic model, directors follow threshold strategies, which are now conditional on the realized $\delta_i$. In particular, any symmetric equilibrium is characterized by two thresholds $(\theta^*_{SH}, \theta^*_M)$, such that director $i$ with signal $\delta_i$ and type $\theta_i$ allocates control to shareholders if and only if $\theta_i > \theta^*_{\delta_i}$. Proposition B.3 shows that while $\theta^*_{SH}$ is always finite, the threshold $\theta^*_M$ can be both finite and infinite. Note that the ex-ante probability that a firm demands shareholder-friendly directors is given by $\tau(\theta^*_{SH}) = \psi(1 - F(\theta^*_SH))$. We call an equilibrium shareholder-friendly if $\tau(\theta^*_{SH}) > 0.5$, i.e., if a shareholder-friendly reputation is rewarded in the labor market.

Proposition B.3

(i) A symmetric equilibrium always exists, and in any symmetric equilibrium $\theta^*_{SH} < \infty$. If $\alpha = 0$ or if the equilibrium is management-friendly, $\theta^*_M$ is infinite.

(ii) In any stable equilibrium, the comparative statics of $\theta^*_{SH}$ with respect to $c$, $\kappa$ and $\alpha$ is the same as in Proposition 3. In addition, $\theta^*_{SH}$ decreases in $\psi$. If $\theta^*_M$ is finite, the comparative statics of $\theta^*_M$ is similar.

Proof. Consider part (i). It is immediate to see that the extended model exhibits strategic complementarity as well. The equilibrium $\theta^*_{SH}$ is determined by the condition

$$\Delta_{SH}(\theta^*_{SH}) = \alpha \lambda (1 - \lambda) (1 - 2\tau(\theta^*_{SH})).$$

$^{32}$In unreported analysis, we also consider an alternative specification, in which the firm demands shareholder-friendly directors whenever shareholders obtain control, even if $\delta_i = M$. The results are qualitatively similar.
Since the right-hand side is bounded and the left-hand side takes all values in \((-\infty, \infty)\), this equation has at least one solution. For a given \(\theta_{SH}^*\), the threshold \(\theta_M^*\) is unique and is given by \(\theta_M^* = \infty\) if \(\Delta_{SH} (\theta_{SH}^*) \geq \Delta_0\) and by \(\theta_M^* = \Delta_{M}^{-1} (\Delta_{SH} (\theta_{SH}^*))\) otherwise. This proves that when \(\alpha = 0\) or when \(\tau (\theta_{SH}^*) \leq 0.5\), then \(\Delta_{SH} (\theta_{SH}^*) \geq 0 \geq \Delta_0\) and hence \(\theta_M^* = \infty\). Note also that since \(\psi > 0\), there is no need to specify off-equilibrium events. These arguments imply that a symmetric equilibrium always exists.

Consider part (ii). To study the comparative statics in the extended setup, we impose the following stability requirement, which is similar to the one in the basic model. We define an equilibrium as stable if the best response function \(\beta_{SH} (\theta_{SH}) = \Delta_{SH}^{-1} (\alpha \lambda (1 - \lambda) (1 - 2 \tau (\theta_{SH}^*)))\) crosses the 45-degree line from above. It follows that in any stable equilibrium, the comparative statics of \(\theta_{SH}^*\) with respect to \(\alpha, c\) and \(\kappa\) is the same as in the basic model.

Note also that \(\theta_{SH}^*\) decreases in \(\psi\) in any stable equilibrium. Intuitively, if shareholder control is more beneficial for the other firm, it is more likely that the board of the other firm will transfer control to shareholders. This increases the value of a shareholder-friendly reputation and gives a director stronger incentives to exert effort. Since \(\theta_M^* = \Delta_{M}^{-1} (\Delta_{SH} (\theta_{SH}^*))\) when \(\theta_M^* < \infty\), the comparative statics of \(\theta_M^*\) is the same as that of \(\theta_{SH}^*\).

Shareholder welfare can be measured by the ex-ante probability that control is allocated efficiently,

\[
W = \psi (1 - F (\theta_{SH}^*)) + (1 - \psi) F (\theta_M^*).
\] (B4)

All else equal, \(W\) increases with \(\theta_M^*\) and decreases with \(\theta_{SH}^*\). Intuitively, control is inefficiently allocated to shareholders when \(\delta_i = M\) and \(\theta_i > \theta_M^*\) and inefficiently allocated to managers when \(\delta_i = SH\) and \(\theta_i < \theta_{SH}^*\).

The equation (B4) shows that the effect of parameters on shareholder welfare can be different depending on whether \(\theta_M^* = \infty\) or \(\theta_M^* < \infty\). Indeed, consider the comparative statics of \(W\) with respect to a parameter \(p \in \{c, \alpha, \kappa\}\). If \(\theta_M^* = \infty\), the comparative statics of \(W\) is the same as in the basic model. However, when \(\theta_M^* < \infty\),

\[
\frac{\partial W}{\partial p} > 0 \Leftrightarrow \frac{\partial \theta_M^*}{\partial p} > \frac{\partial \theta_{SH}^*}{\partial p} \frac{\psi f (\theta_{SH}^*)}{1 - \psi f (\theta_M^*)}.
\]

Since the equilibrium is stable, the signs of \(\frac{\partial \theta_M^*}{\partial p}\) and \(\frac{\partial \theta_{SH}^*}{\partial p}\) are identical and coincide with those of \(\frac{\partial \theta^*}{\partial p}\) in the basic model. Hence, when \(\theta_M^* < \infty\), the effect of these parameters is ambiguous and depends on \(\psi\). For example, \(W\) can actually increase with costs of effort if \(\psi\) is small.
6 Outside candidates

Suppose firms can choose between outside candidates with reputation $\varphi \in \mathbb{R}$. As in the basic model, any equilibrium can be characterized by a threshold $\theta^*$. For any $\varphi$, denote the most and the least shareholder-friendly stable equilibria by $\theta^*_R(\varphi)$ and $\theta^*_R(\varphi)$, respectively. The formal definition of these equilibria is given in Section 3.

Proposition B.4 Let $\varphi$ and $\mathbb{E}[\theta]$ be the expected types of outside candidates. There exist $\varphi$ and $\varphi$, $\varphi < \mathbb{E}[\theta] < \varphi$, such that:

(i) If $\varphi > \varphi$, then $\theta^*_R(\varphi) > \theta^*_R(\mathbb{E}[\theta])$ and $\theta^*_R(\varphi) \geq \theta^*_R(\mathbb{E}[\theta])$.

(ii) If $\varphi < \varphi$, then $\theta^*_R(\varphi) \leq \theta^*_R(\mathbb{E}[\theta])$ and $\theta^*_R(\varphi) < \theta^*_R(\mathbb{E}[\theta])$.

(iii) If $\varphi \leq \varphi \leq \varphi$, then $\theta^*_R(\varphi) = \theta^*_R(\mathbb{E}[\theta])$ and $\theta^*_R(\varphi) = \theta^*_R(\mathbb{E}[\theta])$.

Proof. Suppose that $\theta^*$ is an equilibrium of the model for a given $\varphi$. Let us find the best response function around this equilibrium. There are three possible cases.

First, suppose $\mathbb{E}[\theta|\theta < \theta^*] \leq \varphi \leq \mathbb{E}[\theta|\theta > \theta^*]$. In this case, as in the basic model, a director with a shareholder-friendly (management-friendly) reputation is hired if and only if the other firm is controlled by shareholders (managers), and hence the best response function is $\beta(\theta)$, given by (7).

Second, suppose $\varphi > \mathbb{E}[\theta|\theta > \theta^*]$. Note that a director with reputation $\mathbb{E}[\theta|\theta > \theta^*]$ will never be invited to the board of another firm: a firm controlled by shareholders will always hire the outside candidate with reputation $\varphi$, and a firm controlled by the management will always hire the outside candidate with reputation $\mathbb{E}[\theta]$. On the other hand, a director with reputation $\mathbb{E}[\theta|\theta < \theta^*]$ will always be hired by a management-controlled firm. Using (4), one can show that the best response function of a director changes from $\beta(\theta)$ to

$$\beta^H(\theta) = \Delta^{-1}(\alpha \lambda (1 - \lambda) F(\theta))$$

Finally, suppose $\varphi < \mathbb{E}[\theta|\theta < \theta^*]$. Using similar arguments, a director with reputation $\mathbb{E}[\theta|\theta < \theta^*]$ will never obtain another directorship, while a director with reputation $\mathbb{E}[\theta|\theta > \theta^*]$ will be hired by a shareholder-controlled firm. Hence, the best response function of a director changes from $\beta(\theta)$ to

$$\beta^L(\theta) = \Delta^{-1}(-\alpha \lambda (1 - \lambda)(1 - F(\theta)))$$

12
Let $\bar{\theta}^H$ and $\bar{\theta}^L$ be the largest and smallest fixed points of $\beta^H(\theta)$, respectively. Similarly, let $\bar{\theta}^L$ and $\bar{\theta}^H$ be the largest and smallest fixed points of $\beta^L(\theta)$, respectively. Note that $\beta^H(\theta) > \beta^L(\theta)$ for any $\theta$, and all of these functions are continuous and bounded from above and below. Hence, $\bar{\theta}^H > \bar{\theta}^L(\mathbb{E}[\theta]) > \bar{\theta}^L$ and $\bar{\theta}^H > \bar{\theta}^*(\mathbb{E}[\theta]) > \bar{\theta}^L$.

Define $\varphi \equiv \mathbb{E}[\theta | \theta > \bar{\theta}^H]$ and $\varphi \equiv \mathbb{E}[\theta | \theta < \bar{\theta}^L]$. We next show that these $\varphi$ and $\varphi$ satisfy the statements of the lemma.

Consider part (i). Suppose $\varphi > \varphi$. First, suppose on the contrary $\bar{\theta}^*(\varphi) \leq \bar{\theta}^*(\mathbb{E}[\theta])$. Note that $\varphi = \mathbb{E}[\theta | \theta > \bar{\theta}^H] > \mathbb{E}[\theta | \theta > \bar{\theta}^*(\mathbb{E}[\theta])]$ and that by assumption $\mathbb{E}[\theta | \theta > \bar{\theta}^*(\mathbb{E}[\theta])] \geq \mathbb{E}[\theta | \theta > \bar{\theta}^*(\varphi)]$. Therefore, $\varphi > \mathbb{E}[\theta | \theta > \bar{\theta}^*(\varphi)]$. As shown above, the best response function is then given by $\beta^H(\cdot)$ and since $\bar{\theta}^*(\varphi)$ is the smallest fixed point of $\beta^H(\cdot)$, then $\bar{\theta}^*(\varphi) = \bar{\theta}^H$. However, since $\bar{\theta}^H > \bar{\theta}^*(\mathbb{E}[\theta])$, we get a contradiction with the assumption that $\bar{\theta}^*(\varphi) \leq \bar{\theta}^*(\mathbb{E}[\theta])$.

Second, suppose on the contrary $\bar{\theta}^*(\varphi) < \bar{\theta}^*(\mathbb{E}[\theta])$. This implies that the best response function cannot be $\beta^H(\cdot)$ or $\beta(\cdot)$. Otherwise, since $\bar{\theta}^*(\varphi)$ is the largest fixed point of the best response function, we get $\bar{\theta}^*(\varphi) = \bar{\theta}^H$ or $\bar{\theta}^*(\varphi) = \bar{\theta}^*(\mathbb{E}[\theta])$, respectively, and both would contradict $\bar{\theta}^*(\varphi) < \bar{\theta}^*(\mathbb{E}[\theta])$. Hence, the best response function must be $\beta^L(\cdot)$, which requires that $\varphi < \mathbb{E}[\theta | \theta < \bar{\theta}^*(\varphi)] < \mathbb{E}[\theta]$. This contradicts the fact that $\varphi > \varphi > \mathbb{E}[\theta]$.

Consider part (ii). Suppose $\varphi < \varphi$. First, suppose on the contrary $\bar{\theta}^*(\varphi) > \bar{\theta}^*(\mathbb{E}[\theta])$. Note that $\varphi = \mathbb{E}[\theta | \theta < \bar{\theta}^L] < \mathbb{E}[\theta | \theta < \bar{\theta}^*(\mathbb{E}[\theta])]$ and that by assumption $\mathbb{E}[\theta | \theta < \bar{\theta}^*(\mathbb{E}[\theta])] \leq \mathbb{E}[\theta | \theta < \bar{\theta}^*(\varphi)]$. Therefore, $\varphi < \mathbb{E}[\theta | \theta < \bar{\theta}^*(\varphi)]$. As shown above, the best response function is then given by $\beta^L(\cdot)$ and hence $\bar{\theta}^*(\varphi) = \bar{\theta}^L$. However, since $\bar{\theta}^L < \bar{\theta}^*(\mathbb{E}[\theta])$, we get a contradiction with the assumption that $\bar{\theta}^*(\varphi) > \bar{\theta}^*(\mathbb{E}[\theta])$. Similar to the previous case, this implies that the best response function cannot be $\beta^L(\cdot)$ or $\beta(\cdot)$. Hence, the best response function must be $\beta^H(\cdot)$, which requires that $\varphi > \mathbb{E}[\theta | \theta > \bar{\theta}^*(\varphi)] > \mathbb{E}[\theta]$. This contradicts the fact that $\varphi < \varphi < \mathbb{E}[\theta]$.

Consider part (iii). Suppose $\varphi \in [\varphi, \varphi]$ and consider four possibilities why the statement could be violated. First, suppose on the contrary $\bar{\theta}^*(\varphi) > \bar{\theta}^*(\mathbb{E}[\theta])$. By the same logic as above, since $\bar{\theta}^L < \bar{\theta}^*(\mathbb{E}[\theta]) < \bar{\theta}^*(\varphi)$, the best response function must be $\beta^H(\theta)$, which requires that $\varphi > \mathbb{E}[\theta | \theta > \bar{\theta}^*(\varphi)]$. Since $\bar{\theta}^*(\varphi) = \bar{\theta}^H$, $\varphi > \mathbb{E}[\theta | \theta > \bar{\theta}^H] > \mathbb{E}[\theta | \theta > \bar{\theta}^H] = \varphi$, which is a contradiction. Second, suppose on the contrary $\bar{\theta}^*(\varphi) < \bar{\theta}^*(\mathbb{E}[\theta])$. Since $\bar{\theta}^H > \bar{\theta}^*(\mathbb{E}[\theta]) > \bar{\theta}^*(\varphi)$, the best response function must be $\beta^L(\cdot)$, which requires $\varphi < \mathbb{E}[\theta | \theta < \bar{\theta}^*(\varphi)] = \mathbb{E}[\theta | \theta < \bar{\theta}^L] = \varphi$, which is a contradiction. Third, suppose on the contrary $\bar{\theta}^*(\varphi) < \bar{\theta}^*(\mathbb{E}[\theta])$. Since $\bar{\theta}^H > \bar{\theta}^*(\mathbb{E}[\theta]) > \bar{\theta}^*(\varphi)$, the best response function must be $\beta^L(\cdot)$, which requires $\varphi < \mathbb{E}[\theta | \theta < \bar{\theta}^*(\varphi)] = \mathbb{E}[\theta | \theta < \bar{\theta}^L] = \varphi$, we get a contradiction. Finally,
suppose on the contrary $\theta^* (\varphi) > \theta^* (\mathbb{E}[\theta])$. Since $\theta^L < \theta^* (\mathbb{E}[\theta]) < \theta^* (\varphi)$, the best response function must be $\beta^H (\cdot)$, which requires $\varphi > \mathbb{E}[\theta|\theta > \theta^* (\varphi)] = \mathbb{E}[\theta|\theta > \theta^H] = \varphi$, which is a contradiction.  

7 Contingent reward from additional board seats

In the basic model, a director’s utility from an additional board seat ($\alpha$) is fixed and does not depend either on his type or on the allocation of control in the firm he is invited to. In this section, we relax this assumption and assume that if a director of type $\theta_i$ is hired by a firm with control $\chi_j$, he gets utility

$$\alpha (\chi_j, \theta_i) = \alpha_0 + \alpha_1 (\chi_j, \theta_i),$$

where $\alpha_0 > 0$, $\alpha_1 (\chi_j, \theta_i) > -\alpha_0$, $\alpha_1 (1, \theta_i)$ increases in $\theta_i$ and $\alpha_1 (0, \theta_i)$ decreases in $\theta_i$. Intuitively, the function $\alpha (\chi_j, \theta_i)$ captures the notion that a shareholder-friendly director values an appointment to a shareholder-controlled board more than a management-friendly director, and vice versa. In addition, this function captures the idea that among two potential directors, a shareholder-controlled (management-controlled) firm may offer a higher compensation to the director who is relatively more shareholder-friendly (management-friendly).

Following the arguments in the basic model, a director of type $\theta_i$ finds it optimal to exert effort to transfer control to shareholders if and only if

$$\Delta (\theta_i) \geq \alpha_0 \lambda (1 - \lambda) (1 - 2\tau_j) + \lambda (1 - \lambda) [\alpha_1 (0, \theta_i) (1 - \tau_j) - \alpha_1 (1, \theta_i) \tau_j].$$

Note that the left-hand side increases in $\theta_i$ and the right-hand side decreases in $\theta_i$. Hence, similarly to the basic model, directors follow threshold strategies. By the implicit function theorem and because $\tau_j = 1 - F (\theta_j)$,

$$\frac{\partial \theta_i^*}{\partial \theta_j} = \frac{f (\theta_j) [2\alpha_0 + \alpha_1 (0, \theta_i) + \alpha_1 (1, \theta_i)]}{1_{\lambda(1-\lambda)} \partial \Delta (\theta_i) \big|_{\theta_i=\theta_i^*} - \frac{\partial \alpha_1 (0, \theta_i)}{\partial \theta_i} \big|_{\theta_i=\theta_i^*} F (\theta_j) + \frac{\partial \alpha_1 (1, \theta_i)}{\partial \theta_i} \big|_{\theta_i=\theta_i^*} (1 - F (\theta_j))} > 0.$$

Therefore, the best response function is strictly increasing and hence the game exhibits strategic complementarity as well. Since the best response functions are symmetric, any equilibrium is
symmetric. The comparative statics of $\theta^*$ with respect to $\alpha_0$ in an equilibrium $\theta^*$ shows that

$$\frac{\partial \theta^*}{\partial \alpha_0} = \frac{2F(\theta^*) - 1}{\left(\frac{1}{\lambda(1-\lambda)} \frac{\partial \Delta(\theta)}{\partial \theta} \big|_{\theta=\theta^*} - \frac{\partial \alpha_1(0,\theta)}{\partial \theta} \big|_{\theta=\theta^*} F(\theta^*) + \frac{\partial \alpha_1(1,\theta)}{\partial \theta} \big|_{\theta=\theta^*} (1 - F(\theta^*)) \right) \left(1 - \frac{\partial \theta}{\partial \theta_j} \big|_{\theta=\theta^*}\right)}.$$

In a stable equilibrium, $\frac{\partial \theta}{\partial \theta_j} \big|_{\theta=\theta^*} < 1$ and hence $\frac{\partial \theta^*}{\partial \alpha_0} > 0 \iff F(\theta^*) > \frac{1}{2} \iff \tau^* < 0.5$. Thus, similarly to the basic model, the probability of shareholders getting control increases with directors’ reputational concerns if and only if the equilibrium is shareholder-friendly. The comparative statics with respect to other parameters is similar.
